Any person using or relying on the document for such other purpose agrees, and will by such use or reliance be taken to confirm his agreement to indemnify ECDSWC for all loss or damage resulting there from. ECDSWC accepts no responsibility or liability for this document to any party other than the person by whom it was commissioned.

CONSULTANCY SERVICES FOR HYDROGEOLOGICAL MAPPING USING
REMOTE SENSING, GIS, & GEOPHYSICAL SURVEYING

PHASE II– DEVELOPING GROUNDWATER POTENTIAL MAP

FINAL REPORT

| STRUCTURE OF THE REPORT | |
|--------------------------------|---|
| PHASE - I | INCEPTION REPORT |
| PHASE - II | DEVELOPING GROUNDWATER POTENTIAL MAP |
| Annex I | BURE MUDAYITU WEREDA GROUNDWATER POTENTIAL MAP |
| Annex II | ARGOBA LIYU WEREDA GROUNDWATER POTENTIAL MAP |
| Annex III | DULECHA WEREDA GROUNDWATER POTENTIAL MAP |
| Annex IV | WUCHALE WEREDA GROUNDWATER POTENTIAL MAP |
| Annex V | GIRAR JARSO WEREDA GROUNDWATER POTENTIAL MAP |
| Annex VI | KUYU WEREDA GROUNDWATER POTENTIAL MAP |
| Annex VII | DERA WEREDA GROUNDWATER POTENTIAL MAP |
| Annex VIII | ENEBSIE SAR MIDIR WEREDA GROUNDWATER POTENTIAL MAP |
| Annex IX | SAYINIT WEREDA GROUNDWATER POTENTIAL MAP |
| Annex X | MEKET WEREDA GROUNDWATER POTENTIAL MAP |
| Annex XI | BUGNA WEREDA GROUNDWATER POTENTIAL MAP |
| Annex XII | EBINAT WEREDA GROUNDWATER POTENTIAL MAP |
| Annex XIII | MISRAK BELESA WEREDA GROUNDWATER POTENTIAL MAP |
| Annex XV | TSELEMIT WEREDA GROUNDWATER POTENTIAL MAP |
| PHASE - III | DETAILED SITE SPECIFIC HYDROGEOLOGICAL AND GEOPHYSICAL INVESTIGATION |

Executive Summary

The current study aimed at delineating groundwater potential zones of 14 weredas by using integrated remote sensing and GIS-based multi-criteria evaluation in order to identify promising areas for groundwater exploration. The scarcity of water is a major menace in these 14 Weredas spread over 3 regions of Ethiopia.

In the study, RS (Remote Sensing) and GIS (geographic information system) were utilized to generate five thematic layers (Hydrogeological units, Groundwater recharge, Lineament density, Lineament proximity, and TWI) as factors influencing the groundwater potential. All the thematic layers were then assigned weights according to their relative importance in groundwater occurrence and corresponding normalized weights were obtained based on Saaty's Analytical Hierarchy Process (AHP). Based on the rank assigned by a conceptual understanding of the specific weredas and weights aggregating the thematic maps is done using a weighted overlay method to produce a groundwater potential (GWP) map. The GWP maps are verified by overlay analysis with existing boreholes yield. In addition, Single – Parameter sensitivity analyses are also used to examine effective weights.

The spatial distribution of the project weredas GWP zones generally matches with the conceptual understanding of the project weredas and existing boreholes data during model validation. The good agreement of GWP map and existing well data indicate litho–structural control on groundwater recharge and movement process and factors affecting groundwater recharge were carefully analyzed during the development of thematic layers. Based on the result of sensitivity analysis, the effective weights for each thematic layer show some deviation from empirical weights. The GWP maps produced will be used to quickly identify the prospective GWP zones for conducting site-specific investigations.

This study generally demonstrates that GIS and remote sensing techniques coupled with field data can be used for mapping GWP zones, thereby narrowing down the target areas. Then, by conducting a detailed hydrogeological and geophysical survey at phase III, the 14 most appropriate and 14 optional sites will be selected for drilling.

TABLE OF CONTENTS

| | |
|---|-----|
| 1. INTRODUCTION | 1 |
| 1.1 GENERAL | 1 |
| 1.2 LOCATION OF THE PROJECT LOT-2 | 2 |
| 1.3 OBJECTIVES OF THE STUDY | 4 |
| 1.4 SCOPE OF WORKS | 4 |
| 1.5 GENERAL APPROACH, DELIVERABLES AND PLANNING | 5 |
| 1.6 RISKS AND MITIGATION MEASURES | 7 |
| 2. DATA AND METHODOLOGY OF THE STUDY | 8 |
| 2.1 REMOTE SENSING DATA, FIELD INVENTORY, AND SECONDARY DATA | 10 |
| 2.2.1 Geological mapping method of the study area | 12 |
| 2.2.2 Lineament Extraction method | 13 |
| 2.2.3 Groundwater recharge estimation methods | 14 |
| 2.2.4 Topographic Wetness Index (TWI) generation | 20 |
| 2.2.5 Demography data of the project area | 20 |
| 3. CONCEPTUAL HYDROGEOLOGICAL MODEL OF THE STUDY AREA | 25 |
| 3.1 HYDROGEOLOGICAL CONDITION OF CLUSTER 1 | 25 |
| 3.2 HYDROGEOLOGICAL CONDITION OF CLUSTER 2 | 31 |
| 3.3 HYDROGEOLOGICAL SETUP & CONCEPTUAL MODEL OF CLUSTER 3 | 41 |
| 3.14 HYDROGEOLOGICAL CONDITION OF CLUSTER 4 | 46 |
| 4. RESULT AND DISCUSSION | 59 |
| 4.1 MULTI-CRITERIA DECISION ANALYSIS (MCDA) WEIGHT ASSIGNMENT USING AHP OF EACH WEREDA | 59 |
| 4.2 RECLASSIFICATION OF THEMATIC LAYERS | 76 |
| 4.2.1 HYDRO - LITHOLOGIC UNITS | 76 |
| 4.2.2 GROUNDWATER RECHARGE | 91 |
| 4.2.3 TWI | 106 |
| 4.2.4 LINEAMENT DENSITY | 121 |
| 4.2.5 LINEAMENT PROXIMITY THEMATIC LAYERS | 136 |
| 4.3 OVERLAY ANALYSIS | 151 |
| 4.4 SENSITIVITY ANALYSIS | 151 |
| 4.4.1 SINGLE PARAMETER SENSITIVITY ANALYSIS OF ARGOBA SPECIAL | 151 |

| | |

1. INTRODUCTION

1.1 General

The consultancy contract agreement was signed between the then Basins Development Authority now Ministry of Water and Energy (Client) and Water & Energy Design and Supervision Works Sector In association with AFX OASIS Water Resources & Hydropower Engineering Construction P.L.C (Consultant) on May 14, 2021, for Hydrogeological Mapping by using an integrated approach of geological mapping, remote sensing, weighted GIS overlay analysis, hydrogeological mapping, and geophysical surveying in order to increase the success rate of drilling and provide resilient water sources to communities in selected 14 Weredas of Ethiopia.

It is the initiation of the client to conduct a groundwater study to make groundwater potential maps and to identify drilling target sites for boreholes and alternatives drilling sites in the 14 Weredas of the project area.

The project covers 14 water-scarce weredas known to have complex hydrogeology. The complexity of the hydrogeology is manifested by low and indirect recharge, high salinity groundwater, rugged topography, low yielding shallow groundwater, and very low past drilling success rates.

The current study aimed at delineating groundwater potential zones of 14 weredas by using integrated remote sensing and GIS-based multi-criteria evaluation to identify promising areas for groundwater exploration. The scarcity of water is a major menace in these 14 Weredas spread over 3 regions of Ethiopia for satisfying human needs.

In the study, RS (Remote Sensing) and GIS (geographic information system) were used to generate five thematic layers such as Hydrogeological units, Groundwater recharge, Lineament density, Lineament proximity, and TWI as factors influencing the groundwater potential. All the thematic layers were then assigned weights according to their relative importance in groundwater occurrence and corresponding normalized weights were obtained based on Saaty's Analytical Hierarchy Process (AHP). Based on the rank assigned by a conceptual understanding of the specific weredas and weights aggregating the thematic maps is done using a weighted overlay method to obtain a groundwater potential (GWP) map. The GWP maps are verified by overlay analysis with existing boreholes yield data. In addition, Single –Parameter sensitivity analyses are used to examine effective weights.

The Phase – II report has been prepared based upon field inventory data, remotes sensing data, climatological data and GIS weighted overlay and presented in seven chapters as follows.

Chapter-1: Deals with an introduction to the phase II stage report;

Chapter-2: Data and Methodology of the study

Chapter-3: Conceptual Hydrogeological model of the study area

Chapter-4: Result and discussion

Chapter-5: Revised work plan for Phase – III

Chapter-6: Conclusion and Recommendation,

Chapter-7: References

In this report, for simplification and understanding, the overall weredas are categorized into four clusters based on the geographic location as follows:

Table 1: Clustering of Weredas

| Name | No. of Weredas included | Weredas under the Cluster |
|----------------------|--------------------------------|--|
| Cluster-1 | 3 | Argoba Liyu wereda , Bure Mudayitu & Dulecha |
| Cluster-2 | 4 | Dera, Kuyu, Girar Jarso & Wuchale |
| Cluster-3 | 2 | Sayit & Enebsie Sar Midir |
| Cluster-4 | 4 | Misrak Belesa, Ebenat, Bugna & Meket |
| Without cluster name | 1 | Tselemit |

1.2 Location of the project LOT-2

The proposed study areas are located in Amhara, Afar, and Oromia Regional states, which comprises two weredas in north Gondar (Misrak Belesa & Telemet), two weredas in north Wollo (Bugna & Meket), Ebenet wereda in the south Gonder, Sayit wereda in the south Wollo, Enbise Sar midir in the east Gojam, four weredas in north Shewa zone (Dera, Girar Jarso, Kuyu & Wuchale) and three weredas in the Afar zone 3 (Argoba Liyuzone, Bure Mudayitu & Dulecha) the location of the study areas are depicted in figure 1 below.

The project areas are accessible by a network of dry weather roads and the asphalt road that runs from Addis Ababa – Dejen – Debre Markos - Bahirdar-Gonder and Addis Ababa-Awash-Gewane major asphalt roads. In general, all parts of the project areas are accessible from all directions by several all-weather roads, dry season roads, and footpaths.

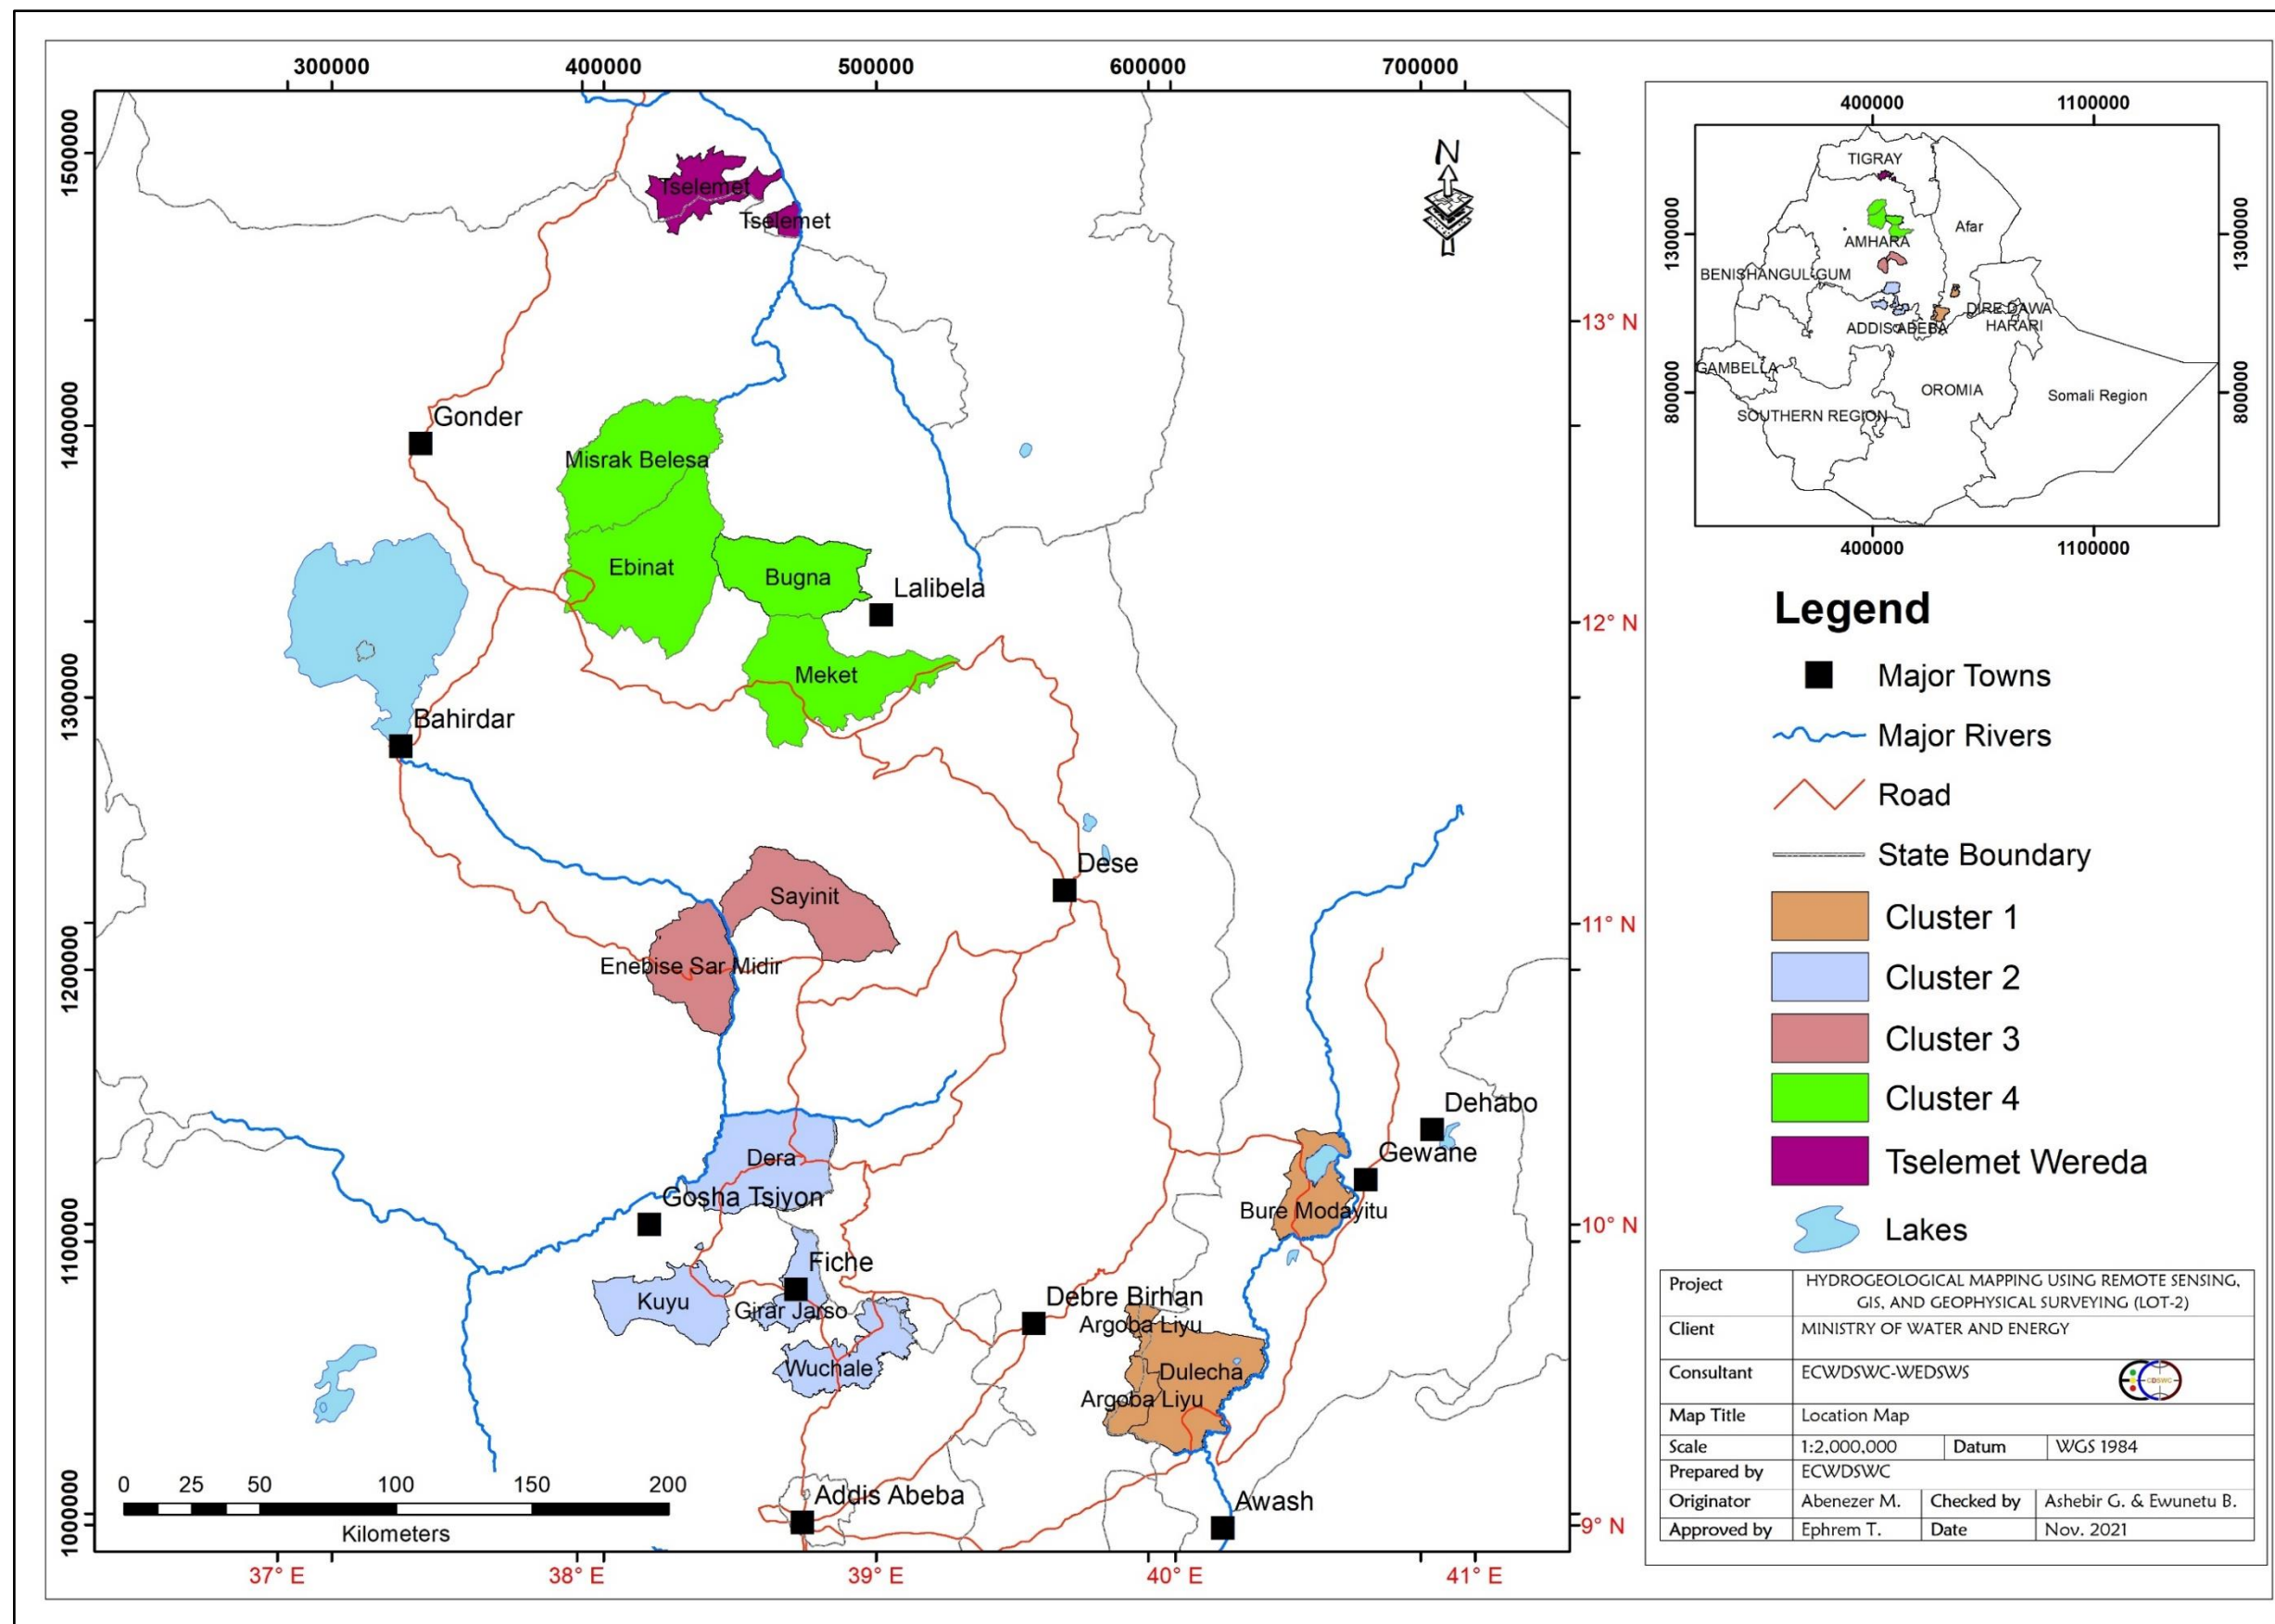

Figure 1: Location of Project areas (LOT-2)

1.3 Objectives of the Study

The main objective of this project is to produce operational hydrogeological maps and recommend drilling sites spread over 3 drought-affected regions of Ethiopia and pinpoint locations with high water demand in combination with high groundwater potential. With the compiled information, associated overlay analyses, and geophysical surveys, 14 most promising drilling sites for groundwater abstraction and 14 alternatives (optional) drilling sites will be selected for each weredas of Lot-2. Generally, the ultimate goal of the climate-resilient WASH project in Ethiopia is to increase access to safe and sustainable water.

The following specific objectives are also associated with the project:

- Carry out National Groundwater Risk Mitigation Strategy and make recommendations.
- Prepare detailed groundwater potential maps for target sites
- Identify one optimal drilling site and one alternative (optional) drilling site per wereda, using these maps and geophysical field investigation, and recommend the type of drilling methodology to be employed.
- Build the capacity of MOWE, Regional governments, and NGOs to use overlay analysis techniques for groundwater potential mapping in Ethiopia.

1.4 Scope of Works

The overall assignment is to carry out the consultancy service for groundwater characterization, Groundwater mapping, and advanced mapping work with internationally known and accepted standards.

The ultimate goal of the project will be to produce operational hydrogeological maps and to identify the most suitable site for drilling. Therefore, this project focused on the preparation of operational hydrogeological maps of 14 weredas of LOT- 2 and identification of target sites for borehole drilling with enhanced drilling success rates and optional drilling sites for each wereda.

1.5 General approach, Deliverables and Planning

The project is designed in three phases to delineate Groundwater potential zones, to prepare operational hydrogeological maps and to select target drilling sites. The technical route is depicted in figure 2 below

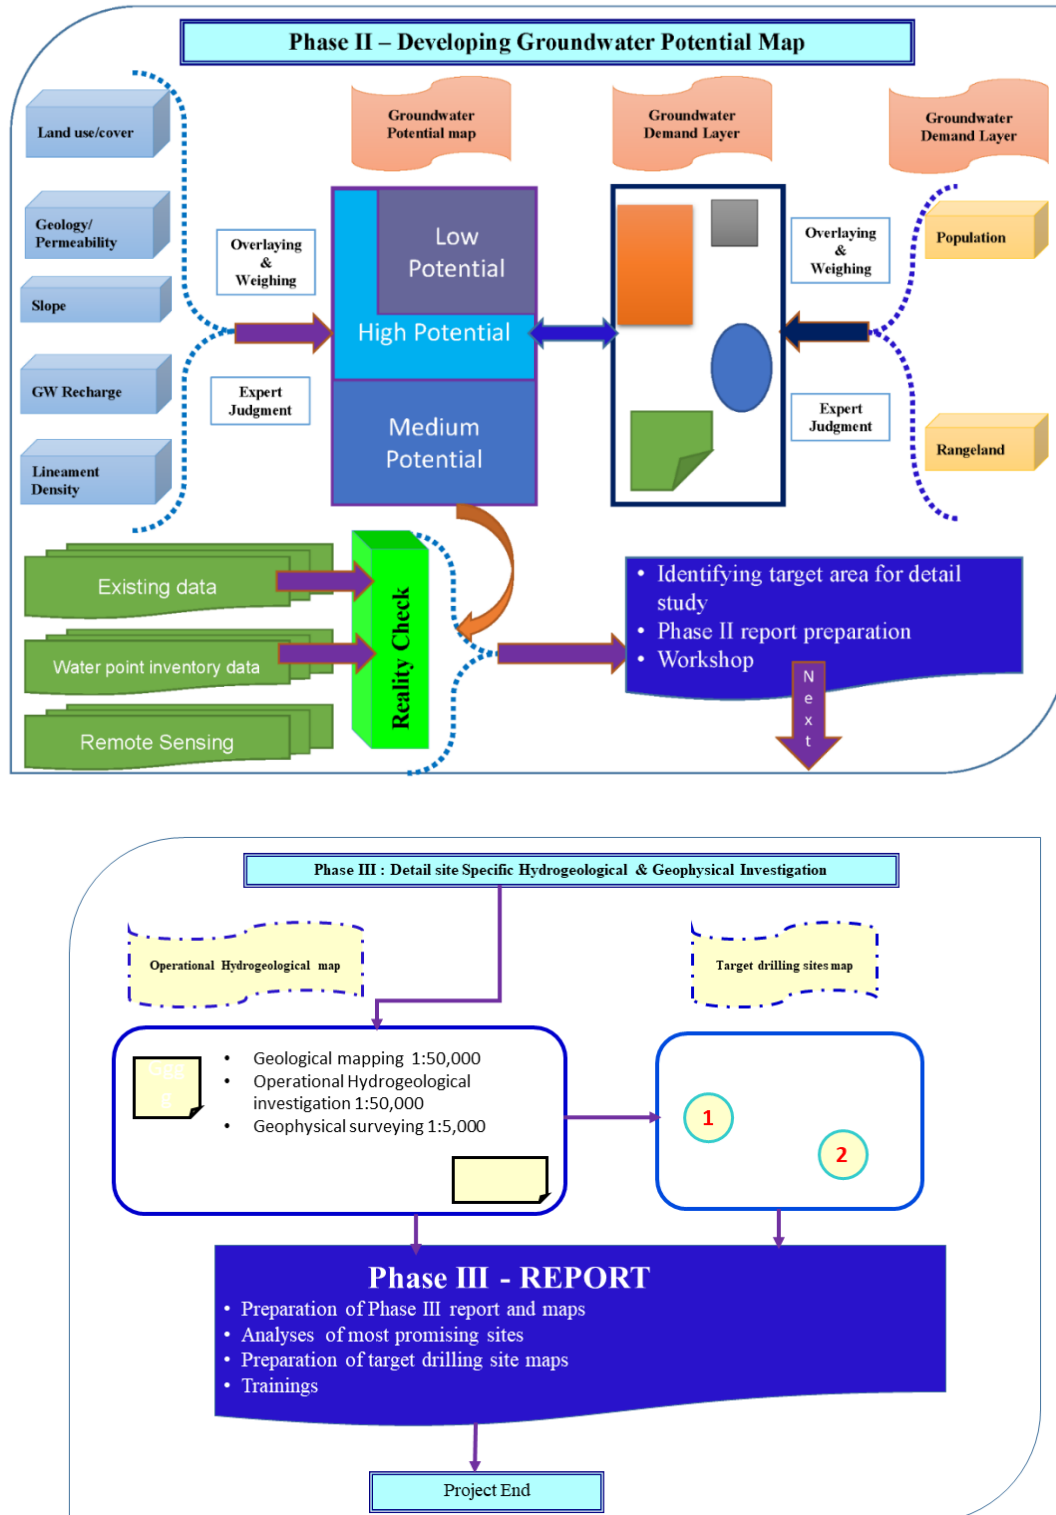

Figure 2: The project phases and the main deliverables

Phase II activities and deliverables

This project was launched on the 24th of May 2021. Since validation and acceptance of Phase I Inception report, the following activities are completed:-

- Field inventory was carried out and basic groundwater data such as SWL, PH, and EC were measured on-site, a water sample was collected for laboratory analysis, available reports were collected from different, government, and private organizations, except Bugna, Meket, and Tselemit weredas due to security problems.
- Climatological datas were collected from NMA and satellite data and also detailed analysis was carried out.
- Hydrological datas were collected from MOWE and detailed analysis was carried out
- Kebeles with Groundwater scarcity were identified by communicating with each weredas water office and target population
- Satellite imagery and maps were acquired and interpreted for land cover mapping, Geological mapping, and lineament extraction of the project weredas.
- Land cover, Soil, Depth to groundwater, Temperature, Rainfall, Wind speed, PET, Elevation maps were prepared.
- Rain days per month, modifying land cover parameter table based on the land cover map was prepared for Groundwater recharge estimation input.
- Groundwater recharge was estimated by using the WetSpss model for the three basins Awash, Abay, and Tekeze basin, and then the Groundwater recharge map was extracted by the respective boundary of each weredas.
- Geological map of 1:100,000 was prepared for each wereda from existing 1:50,000 scale base maps and Satellite images.
- Lineament was extracted from SRTM DEM 30m resolution and Sentinel 1A image radar by using PCI Geomatica software initially, and then the lineament extracted was manually filtered by overlaying road, boundary, and drainage density of project weredas.
- Lineament density and Lineament proximity maps were prepared from extracted lineament
- Topographic Wetness Index was generated for each project weredas
- Hydrogeological sections were constructed for each weredas in order to shows conceptual model.
- Overlay analysis was conducted for the project weredas
- Sensitivity analysis was carried out for the project weredas
- Validation of groundwater potential of each weredas are tested by data of existing boreholes collected.
- Groundwater potential maps were prepared for each weredas
- Phase II report writing and submission

1.6 Risks and mitigation measures

The following anticipated constraints will have an impact on the timely execution of some of the project activities:

- Due to Security issues around the boundary of the Tselemit, Bugna, and Meket Wereda field inventory was not carried out and the model is calibrated by using existing data collected from different organizations.
- Lack and incompleteness of Groundwater data and reports in the Project weredas are observed. The model is validated by using representative data collected during field inventory and existing data collected from different organizations.
- Lack of expert in weredas and Gap in the data handling, storing, and report preparation was observed.

The proposed mitigation measures are depicted as follows: -

- Available Existing data were utilized for validation of the Tselemit, Bugna, and Meket Wereda Groundwater potential maps.
- The data scarcity was filled by collecting existing available hydrogeological information from Wereda and the zone water bureau.
- The capacity building or Knowledge transfer for wereda Hydrogeologist was given and they participated in the groundwater inventory program together with our senior Hydrogeologists.

2. DATA AND METHODOLOGY OF THE STUDY

The study methodology includes various tasks such as preparations for base maps, map updating according to field observations, digitization, and processing of image using software like WetSpas model M1.3, Arc GIS 10.8, Saaty's AHP (K.D. Version 15.09.2018), PCI Geomatica, ESA-SNAP, ERDAS Imagine and ENVI classic software's and interpretation (See figure 3). In this study, RS (Remote sensing) and GIS (geographic information system) methods were used to generate five thematic layers such as Hydrogeological units, Groundwater recharge, Lineament density, Lineament proximity, and TWI as factors influencing the groundwater potential. All the thematic layers were then assigned weights according to their relative importance in groundwater occurrence and corresponding normalized weights were obtained based on Saaty's Analytical Hierarchy Process (AHP). Based on the rank assigned by the conceptual understanding of the specific weredas and weights aggregating the thematic maps is done using a weighted overlay method to obtain a groundwater potential (GWP) map. The GWP maps are verified by overlay analysis with observed borehole yield data. Single – Parameter sensitivity analyses are used to compute effective weights.

Figure 3: Phase II methods and deliverables

2.1 Remote Sensing data, Field Inventory, and Secondary data

Remote Sensing data

The primary issue in the projects (RS) remote sensing and GIS (Geographic Information System) span is identifying sources and availability of spatial input data and acquiring them. The data source could be primary and secondary. The primary sources are acquiring satellite images and interpreting them, field surveys, and generating out of the surveyed data. The secondary sources are previously conducted projects datasets, national and regionally such as CSA, NMA, EGS, and MoWE archives.

The Geospatial data by nature especially when we are dealing with satellite imagery with multiple band spectrums is a huge file size and hence in this project hundreds of gigabytes of data were collected and integrated. The collected data was further explored for its content, quality, consistency, and extent to use for the study as deemed as a decision support system.

The SRTM DEM with the 30-m resolution is used to extract the slope and drainage network. Topographic maps (Scale 1:50,000) from The Ethiopian Mapping Agency (EMA) are also used to digitize relevant features and drainage networks to enhance the raw DEM. Cloud-free Sentinel 2 imager that has a higher spatial resolution (10m) is used to classify land use /cover, SRTM DEM 30m resolution and Sentinel 1 imager using the interferometry approach and ESA-SNAP environment is used to extract lineament for project weredas, SRTM DEM 30m resolution, Landsat-7 ETM + data 30m spatial resolution and Google Earth image at 5m Spatial resolution, Rainfall data was used from CHIRPS, and then the satellite rainfall data was validated by using data collected from 34 metrological stations from the National Meteorological Agency (NMA) of Ethiopia. The mentioned meteorological data is also suggested to be used in Ethiopian climate by different scholars. One of the advantages of CHIRPS products for groundwater recharge estimation is its characteristics of utilizing the land cover type on its algorithm while developing the product. We considered the following additional datasets: elevation, aspect, and slope derived from 30m SRTM DEM, average January and July temperature acquired from JRA - 55, average January NDVI derived from the MODIS (MOD13Q1) data, average July NDVI derived from the MODIS (MOD13Q1) data. We considered the NDVI as a potential additional dataset because the NDVI shows a fast response to precipitation (greening up), which might be more suitable to represent precipitation patterns related to the Monsoon regime i.e. rainfall patterns are seasonal and directional) compared to elevation. For similar reasons, we included aspect and slope because there might be a certain directional pattern in the rainfall distribution.

Field Inventory and Secondary data

In addition to the remote sensing data, Secondary and primary data such as 30 years of climatological data, river discharge data of 21 Hydrometric stations, Demographic data from CSA 2007, FAO soil data, existing groundwater data, water point inventory data, and available Groundwater data and reports are collected analyzed. The Transmissivity and well discharge data were used for validation of Groundwater potential maps. The summarized inventory and existing data are presented in table 2 and the raw data is annexed (2).

Table 2: Inventoried and existing water points

| Wereda | Inventoried water point | | | | Existing water point | | | |
|--------------------|-------------------------|---------------|------------|-----------|----------------------|---------------|-------------|------------|
| | BH | Shallow wells | HDW | Spring | BH | Shallow wells | HDW | Spring |

Preparation of thematic layers

Preparation of thematic layers involves digitizing existing base maps, digital image processing of remote sensing data, and integration of hydrogeological field data. To produce a GWP maps, the thematic layers of lithological units, Groundwater recharge, lineament density, lineament proximity, and TWI were prepared at a scale of 1:100,000 with a spatial resolution of 100m pixel size. After the preparation of the thematic maps, the rank is assigned to each thematic layers attribute based on the conceptual understanding of each weredas, the maps were converted into raster format, and then weighted overlay analyses were carried out according to assigned suitable

weights in the order of their hierarchy process (AHP) (Saaty 1980, 1992) to each thematic layers. Thematic maps for each parameter are prepared as follows.

2.2.1 Geological mapping method of the study area

Geologic map of project weredas are prepared at a scale of 1:100,000 by combining remote sensing and GIS techniques. The methodologies adopted in this work are divided into; (i) Literature review and (ii) Remote sensing and GIS studies.

A literature review was carried out to survey the availability of the geological maps and review of the available geological maps in order to get a general overview of the geology of the area and to identify the gaps and fill these gaps by remote sensing study. The project areas have been mapped by Geological Survey of Ethiopia (GSE) at a scale of 1:50,000 and 1:250,000. These maps gives better information to understand the geological evolution of the project areas. However, these I gaps are identified in GSE maps: -

- (i) Lack of exhaustive Imagery interpretation,
- (ii) Lack of consistency in lithological naming on geological maps,
- (iii) Lack of systematic mapping of litho-stratigraphy, and
- (iv) The significance of the lithology and structural data in establishing and understanding the geological process is not discussed in detail.

The data set used and sources for the interpretation of the remote sensing geological map of the area are shown in the table 3. Image interpretation was made both by computer and on printouts in which all pertinent geological data such as lithologic units, delineation of geological contacts, geological structures (linear features, fractures, and faults), and geomorphological elements are mapped. From the different image combinations, layer stack image, decorrelation, stretch image, and IHS-to-RGB- transformation were selected for their valuable information. The IHS to RGB band 1, 2, 3 images are good in picking tonal and textural differences to identify lithologies. Generally, the Decorrelation stretch (band 6, 4, 2) and IHS-RGB transformation (3, 2, 1) image combination identified possible lithologic units on the project area. Moreover, DEM data were used for geomorphological mapping and tracing major lineaments.

Use of GIS and RS softwares (ArcGIS, ERDAS Imagine, ENVI, Global Mapper, GeoMatica) together with the existing geologic maps were used to prepare the geological map of the project Weredas at a scale of 1:100.000. Geological map of the project wereda is presented in annex (3).

Table 3: Existing geological map and Remote sensing data sources

| No. | Data used | Data source |
|-----|--|---|
| 1 | Topo map @ 1:50,000 and 1:250,000 scale | EMA, 1975 |
| 3 | Geological Maps of Project Sites @ 1:50,000 and 1:250,000 scale | GSE |
| 4 | Shuttle Radar Topography Mission (SRTM), DEM Data @ 30m Spatial Resolution | NASA, & USGS EROS Data Center, 2006 http://glcfapp.glc.f.umd.edu:8080/esdi |
| 5 | ASTER Global Digital Elevation Model (GDEM), DEM Data @ 30m Spatial Resolution | Japan Space Systems (J-space systems) Japan, cooperation with US, 2009 http://gdem.ersdac.jpacesystems.or.jp/search.jsp |

| 7 | Google Earth Image @ 5m Spatial Resolution | US Dept. of State Geographer, 2021 |

2.2.2 Lineament Extraction Method

In this study, two Digital Elevation Models (DEM) sources were used to generate lineaments. The first one is SRTM 30m resolution DEM. The second data source used to generate lineament of the study area is Sentinel 1 imagery using the interferometry approach and ESA-SNAP environment.

As input for the first method, a digital elevation model (DEM) was obtained from SRTM. The study area covers 12 DEM Tiles in total and all the tiles were mosaic in the ArcGIS software environment.

Lineament extraction process from SRTM DEM 30m resolution

The lineament extraction process was carried over the overlaid shaded relief images with multi-illumination directions of (0°, 45°, 90°, and 135° azimuth and sun angle of 30°). PCI Geomatica software was also used for the automatic lineament extraction. These steps were carried out under the different thresholds, and then lineament extracted was manually filtered by overlaying hill shade, drainage density, and road map of the project weredas.

DEM extraction process from Sentinel - 1 Imagery using Interferometry approach and ESA-SNAP

The second option checked for the lineament extraction is Sentinel 1 using the interferometry approach. We download the Sentinel 1A image and generate DEM, The DEM is used to generate hillsides and extract lineament in PCI GeoMatica. The same parameter, process, and azimuthal angle are applied to the hill shade which is generated from the sentinel 1 image. PCI GeoMatica with different threshold parameters was used to extract the lineaments.

Therefore, the final generated lineament from Sentinel imagery was manually filtered by overlaying hill shade, drainage density, and road map of the project weredas. Generally, the lineament extracted by using SRTM DEM 30m and Lineament extracted from Sentinel 1A image

were validated by ground-truthing and by comparing with the existing 1:250,000 geological map of the project wereda.

2.2.3 Groundwater recharge estimation Method

In this study, the Hydrological study was conducted by considering the overall hydrological connectivity of the basin; hence it was important to consider all weredas upstream hydrological characteristics, particularly for all wereda where Main River crosses its boundary by considering the recharging source could be the cumulative effect both the drainage within wereda or rivers crossing each wereda. As the result, all upstream portions of the selected wereda were considered.

Data used for Groundwater Recharge estimation

The water balance quasi-steady-state model (WetSpass) requires a set of input data, that encompasses meteorological data (temperature, precipitation, wind speed, and potential evapotranspiration), distributed groundwater depth, topography (DEM and slope), land use/land cover, and soil types of the four clusters in Awash, Abay and Tekeze River Basins (Ampe et.al. 2012). A list of data that was used as input after resampled into 100m by 100m is presented in table 4. The spatial representation of land use, soil, Rainfall, Temperature, wind speed, PET and Elevation maps, and modified land use, soil, and rain days per months parameter tables used as an input for the model is presented in phase III water balance reports.

Table 4: Dataset used for the evaluation of groundwater recharge

| S. N | Input data | Data name | Resolution | Period | Description |
|------|------------------------------|----------------------------|---------------|------------|--|
| 1 | Rainfall | CHIRIPS | 0.25°x 0.25° | 1980- 2019 | Climate Hazards Group Infrared Precipitation with Station data (CHIRPS) designated by incorporating multi-source infrared sourced product. CHIRPS rainfall products and some Spatio-temporal analyses of rainfall using CHIRPS over Ethiopia and other Eastern-Africa regions indicates a potential to be used for various applications (Fenta. A, et. al., 2012; Ayehu, G, et.al. 2018; Maidment. R, et. al., 2013) |
| 2 | Temperature | JRA-55 | 0.56° x 0.56° | 1958-2019 | Japanese global atmospheric reanalysis project, where The Japan Meteorological Agency (JMA) conducted the second Japanese global atmospheric reanalysis, called the Japanese 55-year Reanalysis or JRA-55. Kobayashi et al. ,2015) |
| 3 | Wind speed | ECWF-ERA5 | | 1979-2019 | |
| 4 | Potential evapotranspiration | Calculated | 30 km x 30km | | penman-monteith and modified penman-monteith (for open water) used for calculation of PET |
| 5 | Groundwater depth | Historic GW data by ECDSWC | | | |
| 6 | Slope | SRTM | 30m X 30m | -- | SRTM (Shuttle Radar Topography Mission) DEM is a unique product that was produced by NASA and NGA in cooperation with the German and Italian space agencies. The slope of the study area is derived from this high-resolution digital elevation model. |
| 7 | Land use/ land cover | Esri | 10mx 10m | 2020 | The recent land use-land cover (2020G.C) was used for the analysis. This layer displays a global map of land use/land cover (LULC). The map is derived from ESA Sentinel-2 imagery at 10m resolution. It is a composite of LULC predictions for 10 classes throughout the year in order to generate a representative snapshot of 2020 |
| 8 | Soil | FAO | | | Harmonized World Soil Database v 1.2 and supervised in the Ethiopian context |

Groundwater Recharge Estimation Method

Three software or models were used for the study. Spatially distributed water balance quasi-steady-state model (WetSpass), programming language(R) software that is designed for statistical computing and graphics, and geographical information systems (GIS) for analysis and presenting results. The WetSpass stands for water and energy transfer among plants, soil, and atmosphere. A physically-based WetSpass model is usually applied to assess long-term mean spatial pattern and characteristics of recharge, surface runoff, and actual evapotranspiration. In this project, the main target of the WetSpass model is to evaluate the monthly recharge of selected wereda and eventually to understand long term mean annual recharge of the chosen weredas.

As the main task of hydrological analysis is to estimate groundwater recharge in the proposed wereda, the tool commonly recommended for spatial-based groundwater recharge estimation too, WetSpass model were applied. The WetSpass model treats a basin or region as a regular pattern of raster cells. Every raster cell is further sub-divided in a vegetated, bare soil, open water, and impervious surface fraction, for which independent water balance is maintained.

The total water balance per raster cell and hydrological season, calculated as follows: -

$$E_{\text{raster}} = a_v ET_v + a_s E_s + a_o E_o + a_i E_i \text{-----Eq.1}$$

$$S_{\text{raster}} = a_v S_v + a_s S_s + a_o S_o + a_i S_i \text{-----Eq.2}$$

$$R_{\text{raster}} = a_v R_v + a_s R_s + a_o R_o + a_i R_i \text{-----Eq.3}$$

Where the index raster refers to raster cell, with ET_{raster} , S_{raster} and R_{raster} respectively, the total evapotranspiration, surface runoff and recharge in a raster cell and a_v , a_s , a_o and a_i respectively the vegetated, bare soil, open water, and impervious area fractions of a raster cell.

The geographic information system (GIS) tool was used for re-sampling and mapping of both input and output parameters. Among four common techniques of re-sampling or adjusting meteorological data resolution, bilinear methods were used to adjust the resolution of precipitation, temperature, and wind speed data towards 100 by 100 meters based on client interest. Overall schematic representation of the applied methodology is presented in figure 4 below:

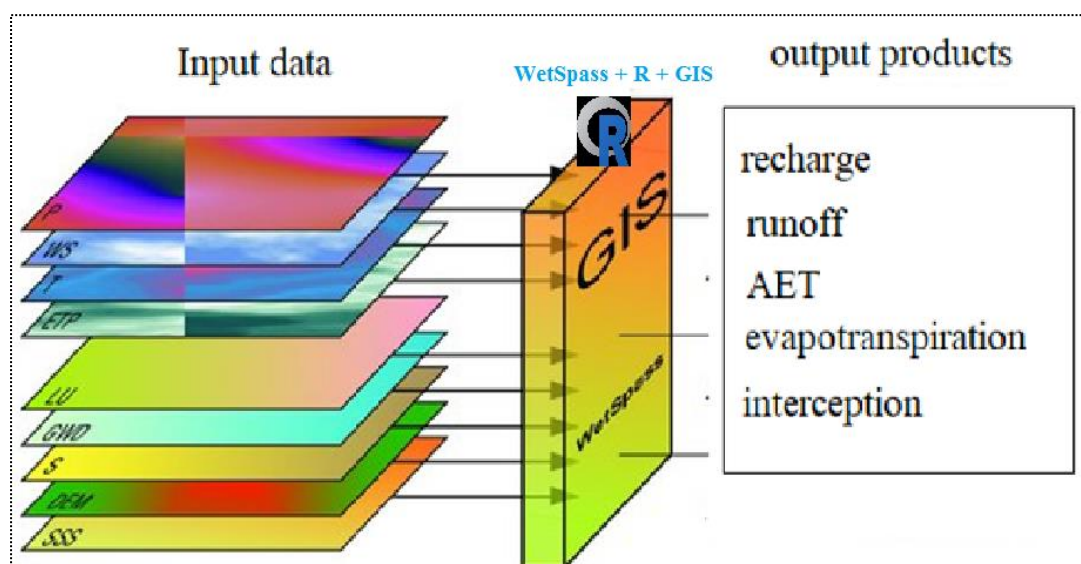

Figure 4: Schematic representation of model used for the study

Land cover data Extraction method

Downloading and processing raster data for land cover classification

Cloud-free Sentinel 2 imagery that has a higher spatial resolution (10 m) is used for LULC image classification. In this stage over 18 sentinels - 2b images were downloaded and pre-processed (geometrically and radio metrically corrected using QGIS software semi-automatic classification (SCP) plugin. In addition, each image was mosaic, enhanced, and resampled using the nearest-neighbor sampling technique in ERDAS IMAGINE Software. All the resampled images were mosaicked for further process (sub setting, LULC reclassification) using ENVI classic software.

Side by side while capturing fresh primary land cover classification techniques used above, for this project the ESRI land cover of 2020 is used as input. In 2020 ESRI developed a global land cover map from ESA Sentinel-2 10m resolution image and classified it into 10 classes. The originator of the data is suggested to use the dataset for food security, hydrologic modeling, conservation planning, and other related investigations. And hence this dataset will be explored and integrated into our hydrologic modeling with supplements from the land use/cover data generated through the methodologies indicated above.

Therefore, we reclassified the LULC map of ESRI based on our methodology, it was reclassified in 8 classes using Arc GIS reclassification techniques.

Therefore, we reclassified the LULC map of ESRI based on our methodology, it was reclassified in 8 classes using Arc GIS reclassification techniques.

- i. Convert raster data into vector
- ii. Take an AOI for an additional LULC class, for instance, forest. This class was not included in the ESRI LULC classification
- iii. Convert the vector into a raster
- iv. Reclassify the raster data with the newly generated LULC classes

Accuracy assessment of supervised classification methods for the re-classified LULC

Accuracy assessment is an important part of any classification project. It compares the classified image to another data source that is considered to be accurate or ground truth data. Thus, high-resolution imagery (Sentinel-2 and Google earth images) was applied for Ground Truth. The accuracy assessment has been done for each wereda over the project area.

The accuracy assessment aims to provide an index of how closely the derived class allocations depicted in the thematic land cover map represent reality. In essence, the summary metrics of accuracy provide a measure of the degree of correctness in the class allocations in the map. Attention is, therefore, focused on thematic accuracy. The confusion matrix is well suited to this task (Table 5). The cases that lie on the main diagonal of the matrix represent those correctly allocated, while those in the off-diagonal elements represent errors. Two types of thematic error, omission, and commission, are possible and both may be readily derived from a confusion matrix (Congalton and Green, 1999). An error of omission occurs when a case belonging to a class is not allocated to that class by the classification. Such a case has been erroneously allocated to another class, which suffers an error of commission.

The most common way to assess the accuracy of a classified map is to create a set of random points from the ground truth data and compare that to the classified data in a confusion matrix. The assessment was done using ArcGIS software.

Checked the error matrix with the formula (Accuracy in % = total true value/total sample value*100) and the total accuracy is 92.22% which is very good.

Table 5: confusion matrix over true values in the project wereda.

| OBJECTID | Predicts | Class1 | Class2 | Class3 | Class4 | Class5 | Class6 | Class7 | Class8 | Total True Value | Total Sample Value | Total Accuracy % |
|----------|----------|--------|--------|--------|--------|--------|--------|--------|--------|---|--------------------|------------------|
| 1 | 1 | 16 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | | | |
| 2 | 2 | 0 | 20 | 0 | 4 | 0 | 0 | 0 | 0 | | | |
| 3 | 3 | 0 | 0 | 37 | 0 | 0 | 0 | 0 | 0 | | | |
| 4 | 4 | 0 | 5 | 0 | 16 | 0 | 0 | 0 | 0 | | | |
| 5 | 5 | 0 | 0 | 0 | 0 | 29 | 1 | 0 | 0 | | | |
| 6 | 6 | 0 | 0 | 0 | 2 | 0 | 24 | 0 | 1 | | | |

Land cover/land use map with 92.22 accuracy was prepared and used as an input file for groundwater recharge estimation.

Normalized difference vegetation index (NDVI)

Vegetation indices are a staple remote sensing product and the normalized difference vegetation index (NDVI) is the most widely used vegetation index. The NDVI is a standardized index allowing to generate an image displaying greenness (relative biomass). This index takes advantage of the contrast of the characteristics of two bands from a multispectral raster dataset—the chlorophyll pigment absorption in the red band and the high reflectivity of plant materials in the near-infrared (NIR) band.

NDVI measures the ratio of the reflective difference in the red and near-infrared portions of the spectrum to the sum of red and near-infrared reflectance. Green, healthy vegetation reflects light in the near-infrared portion of the spectrum and absorbs red light, and ranges from values of 1.0 to -1.0 where larger, positive values indicate green vegetation.

One of the input spatial layers for the hydrogeology study is NDVI. To calculate NDVI the inputs are availing appropriate imagery and a program that allows interaction with the image data. QGIS is a great, free option for a GIS program that provides the tools to display, analyze and present remotely sensed data. The following steps below are followed in QGIS and its toolbox environment to calculate NDVI for the project weredas and sample main screenshots were added as pictures for demonstration purposes. As usual, the process started by downloading sentinel 2 images of required bands and used as input for the processing.

- i. Open stacked sentinel 2 images in QGIS.
- ii. FOR NDVI calculation we are using NIR (band 8) and red (band 4)
- iii. Use the raster calculator in QGIS is to calculate NDVI.
- iv. $NDVI = \frac{NIR-RED}{NIR + RED}$

Then the resulting NDVI is classified for visualization purposes and shown in the figure below

Figure 5: calculated NDVI using QGIS

2.2.4 Topographic Wetness Index (TWI) generation

TWI (also known as the compound topographic index (CTI)) is an indicator that measures the potential on where water tends to accumulate. A high index value indicates a high potential of water accumulated due to a low slope and vice versa.

Typically, the raw TWI indicators range from -3 to 30. The TWI is a unique tool that allows the user to identify areas that could be:

- Identifying the area adversely affected by ponding and flooding caused by rainfall events
- Can provide planners a visual mechanism for site selection of green infrastructure projects
- The identification of areas with increased susceptibility to ponding due to sewer overflow or basement back-ups

The equation given below was used for the estimation of TWI.

$$TWI = \ln \frac{\alpha}{\tan \beta} \text{-----Eq.4}$$

α = upslope contributing area; β = Topographic gradient (Slope)

2.2.5 Demography data of the project area

According to the report from the Central Statistical Agency Population Projection of Ethiopia for all Regions at wereda Level, July 2021

In order to estimate water demand knowing the population growth rate is very important. Accordingly, the population of Project Weredas is estimated based on to grow at the rate of each region annually in accordance with 2025, 2030 & 2035 CSA estimates of population growth rate for the Oromia region, Afar region, and Amhara region respectively. The projection is based on exponential growth rate model which goes, $P_t = P_o e^{r\Delta t}$

When: P_t = Population at t year, P_o = Population at current (initial) year

$e = \ln 10 = 2.718$, Δt = the difference between t year and initial year

Therefore, based on the above exponential population projection formula, the current population size of each project Weredas is projected for the planning period 2035 and the summarized population size is presented in the following tables.

Table 6: Population size of Girar Jarso wereda, July 2021 to 2035

3. Conceptual Hydrogeological model of the study area

3.1 Hydrogeological condition of Cluster 1

The study area falls in the middle of the Awash River valley. The hydrogeological conditions of the area depend on the geology, geologic structures, and geomorphology of the area. The study areas are mainly covered by unconsolidated sediment, acidic, intermediate, and basic volcanic rocks covered by thin soil. Alluvial, Ignimbrite, rhyolite, and basalt are the main volcanic rocks of the study area. They are jointed, fractured, and affected by dense weathering.

The geomorphological setup of the study areas are characterized by a series of horst and graben. According to previous studies and hydrogeological set up of the areas, the major sources of recharge for the study areas (Weredas) are:

- Subsurface inflow from western and eastern fractured volcanic rocks,
- precipitation induced within the study areas
- Infiltration from surface rivers and overland flows (river banks infiltration)
- subsurface inflow from the intermountain valley of eastern Amhara region

In addition, geomorphological setup, water level observed, geologic structures, groundwater contour, and conceptual model developed in previous studies (WWDSE, 2011) shows that groundwater recharged at western and eastern highland areas flow toward rift floor (Dulecha and Bure Mudayitu wereda) and mixed up with groundwater recharge from surface rivers and rainfall-induced in the area and heads northward in an almost parallel way with Awash river.

The hydrogeological setup of each wereda is discussed preliminary as follows:

Conceptual Hydrogeological model of Argoba Liyu Wereda

Argoba Liyuwereda is located on the west margin of MER above major faults that separate the rift floor from western highland areas. Topographically, Argoba Liyu wereda is rugged and slopy and several streams arise from this wereda and flow toward the rift floor. Most of this wereda is covered by Cenozoic volcanic rocks such as rhyolite and basalts. These units are affected by NE and NNE trending faults and lineaments are also observed in these formations.

As depicted on the hydrogeological map and also cross-section constructed along the groundwater flow path to conceptualize groundwater flow and storage in this wereda (Figure 6 and 7) and also stated in previous works (WWDSE, 2011), Argoba Liyuwereda and its vicinities are mainly recharged from direct rainfall-induced within the area and also both the recharged groundwater and overland flow the area flows toward the adjacent low land.

From a hydrogeological point of view, most areas of Argoba Liyuwereda exposures are favorable for groundwater recharge, storage, and movement due to the existence of primary and secondary porosities. However, groundwater recharge in the area flows toward the lowland/rift floor through main fractures due to high head differences.

Conceptual Hydrogeological model of Dulecha Wereda

Dulecha wereda is located partly in Awash graben of MER. It is bounded by the Awash river gorge in the east and Argoba Liyu wereda and major marginal faults in the west direction. Topographically, the eastern part of Dulecha wereda is plain. However, the plain slightly up to an elevation of more than 1500 meters on the western margin (escarpment) of wereda.

Alluvial deposits and volcanic rocks, mainly Ignimbrite and basalts affected by numerous geologic structures are the main formations observed in the area. From a hydrogeological point of view, existences of tectonically impacted hydrogeologic units are deemed crucial for the occurrence and storage of groundwater.

According to previous studies (WWDSE 2011) and also current finding shows that groundwater of Dulecha wereda and its vicinity is recharged from subsurface flow from the western volcanic highland areas, surface rivers, and rainfall-induced within the area and flows toward north direction parallel to Awash river (Figure 6). In addition, surface runoff from the adjacent elevated areas also recharges groundwater of the area as shown on the hydrogeological cross-section constructed along the groundwater flow path (Figure 7). Moreover, two main aquifers named unconsolidated alluvial and fractured volcanic rocks aquifers are identified in Dulecha wereda and adjacent graben located east of Dulecha wereda.

Conceptual Hydrogeological model of Bure Mudayitu Wereda

Bure Mudayitu Wereda is topographically plain in the east and rises slightly up to an elevation of more than 1000 meters on the western escarpment. The plain is dominated by lacustrine deposits. Whereas, areas close to the foot of the escarpment are covered with coarser alluvial deposits.

As observed from superficial deposits and lithological logging of the drilled borehole in Buri kebele of Bure Mudayitu wereda (ECDSWC, 2021), lacustrine deposits and clay that has a thickness of more than 460 meters exists. The thickness of lacustrine deposits decreases close to the foot of the escarpment and fractured volcanic rocks are encountered at shallow depth (32 meters) during drilling of Dengeligita borehole.

Most part of this wereda is swampy and covered by vegetation. According to a previous study conducted for Tendaho irrigation by gauging Awash river flow at Awash and Adaitu stations (WWDSE 2013), 400 MCM to 3076 MCM water losses are observed at Gedebassa swam complex of Bure Mudayitu wereda by evaporation and infiltration towards the ground. However, hydrogeologic units exposed in most parts of this wereda are not good enough in terms of groundwater infiltration, flow, and storage.

According to an inventory conducted, boreholes drilled on plain areas of this wereda are either dry or saline due to the existence of lacustrine deposits. This fact is supported by a number of one-dimensional VES conducted by ECDSWC (2019) for water supply well sittings that show the existence of geo-electric units that exhibit very low apparent resistivity response. According to the developed conceptual model (Figure 9), Bure Mudayitu wereda and its vicinity groundwater is recharged mainly from subsurface flow from west highland including subsurface inflow from the intermountain valley of eastern Amhara region area through Jewaha outlet, subsurface inflow from southern areas, and surface rivers (mainly Awash River) and flow towards the northeast direction (Figure 8).

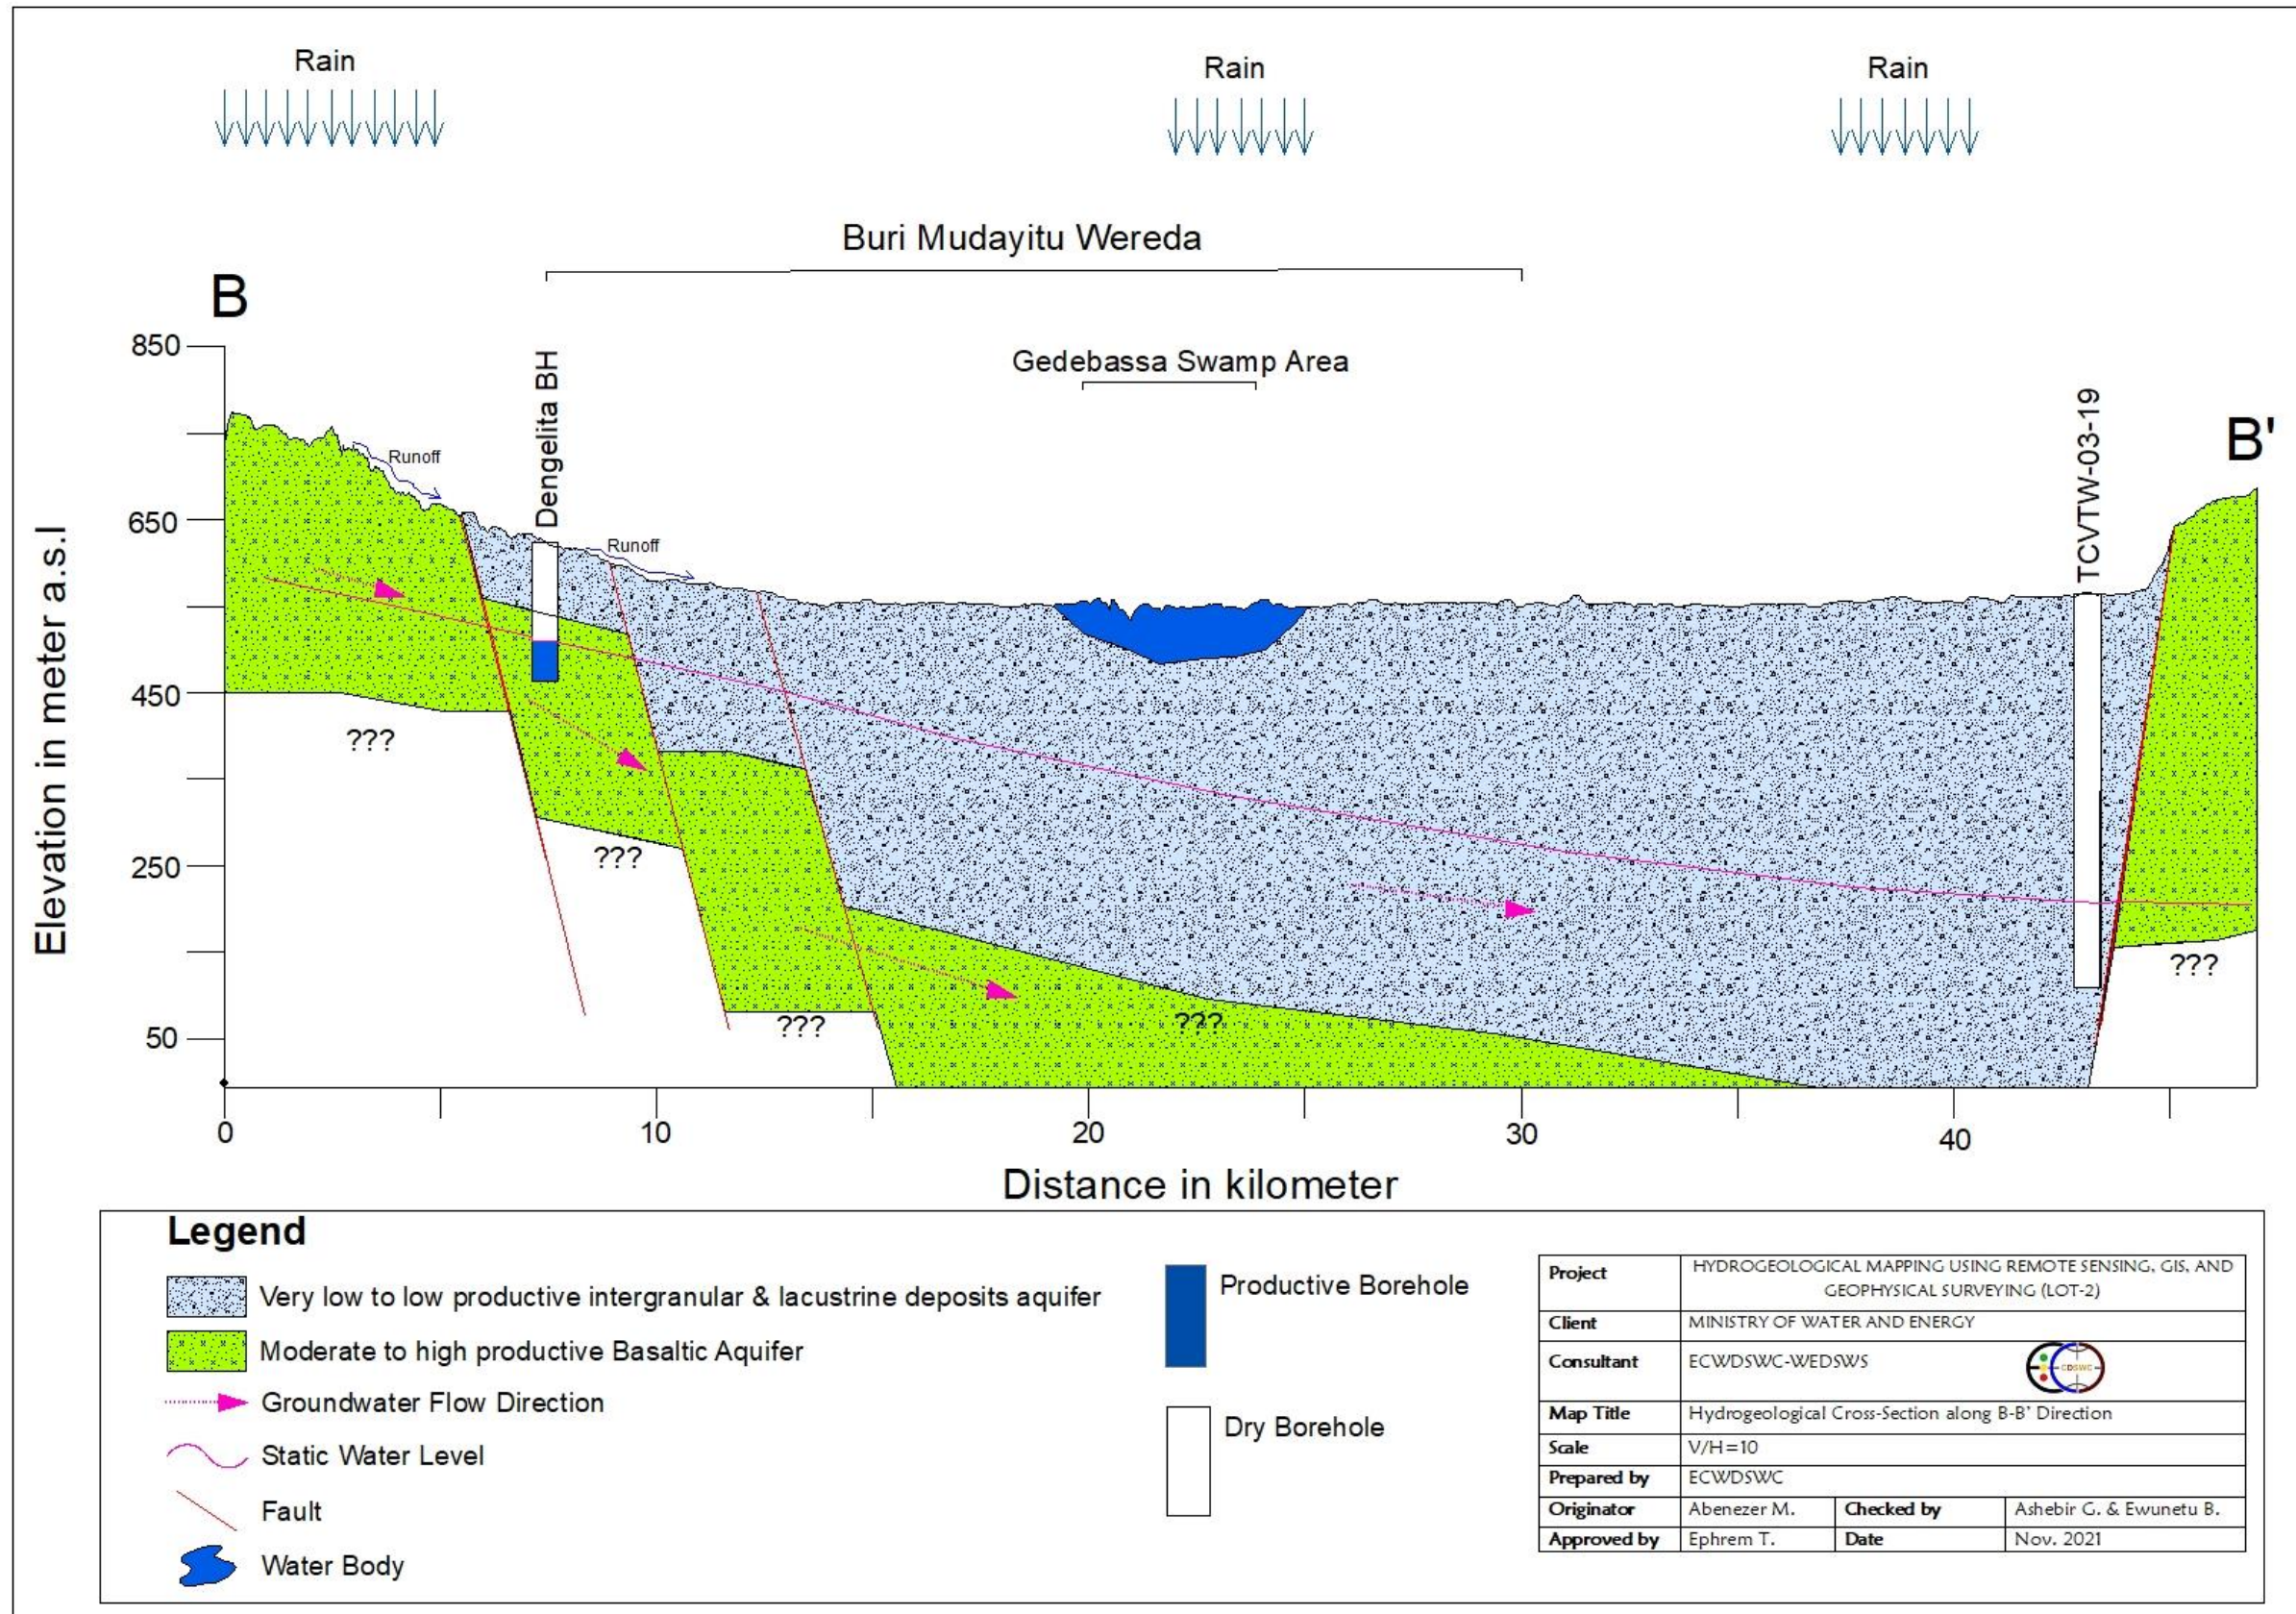

Figure 9: Hydrogeological cross – section along B-B' Direction

3.2 Hydrogeological condition of Cluster 2

Based on hydraulic characteristics of rock units, spring discharge, depth to the groundwater, mode of recharge, and groundwater intake to their system, the Hydrogeological condition of Wuchale, Girar Jarso, Kuyu, and Dera weredas are conceptualized and discussed as follows:

Conceptual Hydrogeological model of Wuchale wereda

Wuchale wereda is located partly in the Jema sub-basin and partly in the mugger sub-basin. Topographically, Wuchale wereda is plain land. Most part of the wereda is covered by alluvial deposits and volcanic rocks, mainly Aiba and Tarmaber basalts. The yield and transmissivity of boreholes drilled in this wereda revealed that the intergranular alluvial aquifer and the basaltic aquifer have moderate to very high groundwater potential due to primary and secondary permeability of the lithological units exposed in the area.

As depicted on the hydrogeological map and also cross-section constructed along the groundwater flow path to conceptualize groundwater flow and storage in this wereda (Figure 10 and 11), the local geomorphic setup and subsurface configuration of permeable and impermeable rock units control the depth and pattern of groundwater circulation in the area. The E-W oriented horst of the impermeable mudstone underlying the Tertiary volcanics control aquifer distribution into Muger and Upper Awash groundwater sub-basin where surface water and groundwater divides do not coincide.

The elevation of depth to groundwater level in hand-dug wells and deep boreholes shows that groundwater tapped by hand-dug wells and deep boreholes is in different flow systems. The elevation of depth to water levels in hand-dug wells is very near the surface and represents the local groundwater sub-system in the upper water-table aquifer that discharges to the nearest surface water bodies or infiltrates downward and recharges the basaltic aquifer underneath.

Conceptual Hydrogeological model of Girar Jarso wereda

Girar Jarso wereda is located partly in the Jema sub-basin and partly in the mugger sub-basin. Topographically, the southern part of Girar Jarso wereda is plain land and the northern part is a rugged and sloppy topographic setup. Most part of the wereda is covered by volcanic rocks, mainly Ashangi basalt, Alaje formation, Aiba and Tarmaber basalts, and sedimentary rocks such as Upper sandstone, Muger mudstone, Limestone, and Lower sandstone.

The yield and transmissivity of boreholes drilled in this wereda revealed that the Aiba and Tarmaber basaltic aquifer has moderate to high groundwater potential due to secondary permeability of the lithological units exposed in the area. Besides in the northern part of the wereda at the contact between Ashangi basalt and Muger mudstone spring with the low discharge of 1.6l/s.

As depicted on the hydrogeological map and also cross-section constructed along the groundwater flow path to conceptualize groundwater flow and storage in this wereda (Figure 12 and 13), the local geomorphic setup and subsurface configuration of permeable and impermeable rock units control the depth and pattern of groundwater circulation in the area. The E-W oriented horst of the impermeable mudstone underlying the Tertiary volcanic control aquifer distribution into Jema and Upper Awash groundwater sub-basin where surface water and groundwater divides do not coincide.

The elevation of depth to groundwater level in hand-dug wells and deep boreholes shows that groundwater tapped by hand-dug wells and deep boreholes is in different flow systems. The

elevation of depth to water levels in hand-dug wells is very near the surface and represents the local groundwater sub-system in the upper water-table aquifer that discharges to the nearest surface water bodies or infiltrates downward and recharges the basaltic aquifer underneath.

Conceptual Hydrogeological model of Kuyu wereda

Kuyu wereda is located in the Muger sub-basin. Topographically, the Northern part of Kuyu wereda is plain land and the southern part is a rugged and sloppy topographic setup. Most part of the wereda is covered by volcanic rocks, mainly Aiba and Tarmaber basalts and sedimentary rocks such as Upper sandstone, Muger mudstone, Limestone, and Lower sandstone.

The yield and transmissivity of boreholes drilled in this wereda revealed that the intergranular alluvial aquifer and the basaltic aquifer have moderate to high groundwater potential due to primary and secondary permeability of the lithological units exposed in the area. Besides in the southern part of the wereda at the contact between Antalo limestone and Muger mudstone springs with the moderate discharge of 2 and 4 l/s.

As depicted on the hydrogeological map and also cross-section constructed along the groundwater flow path to conceptualize groundwater flow and storage in this wereda (Figure 14 and 15), the local geomorphic setup and subsurface configuration of permeable and impermeable rock units control the depth and pattern of groundwater circulation in the area. The E-W oriented horst of the impermeable mudstone underlying the Tertiary volcanic control aquifer distribution into Muger and Upper Awash groundwater sub-basin where surface water and groundwater divides do not coincide.

Conceptual Hydrogeological model of Dera wereda

Dera wereda is located in the Jema sub-basin and the western part surrounded by the Abay River. Topographically, the central and southern central part of Dera wereda is plain land, and surrounding the central and southern central part is rugged, gorge and sloppy topographic setup. The central and southern central part of the wereda is covered by volcanic rocks, mainly Aiba and Tarmaber basalts, and the surrounding central part in Abay and Jema river gorge sedimentary rocks such as Upper sandstone, Muger mudstone, Limestone, and Lower sandstone exposed.

The yield and transmissivity of boreholes drilled in this wereda revealed that the basaltic aquifer has moderate groundwater potential due to the secondary permeability of the lithological units exposed in the area. Surrounding the central and southern central part of Dera wereda there is no spring, BH, and their no sub-surface information in limestone, Gypsum, upper and lower sandstone formations.

As depicted on the hydrogeological map and also cross-section constructed along the groundwater flow path to conceptualize groundwater flow and storage in this wereda (Figure 16 and 17), the local geomorphic setup and subsurface configuration of permeable and impermeable rock units control the depth and pattern of groundwater circulation in the area.

3.3 Hydrogeological setup & Conceptual model of cluster 3

Conceptual model of Enebise Sar Midir and Sayit Weredas

After integration of existing data analysis was carried out and conceptual setup was made to verify the groundwater system of the study areas.

In Enebise Sar Midir wereda the collected data shows that the wells discharge are ranging from 0.2 to 10 l/s with a maximum depth of 181m. Depth to water level decreases (comes up) from north-west to south-east direction. The lithological log of these boreholes of the area generally shows that on the top part (0 - 20) meters depth soft formations, in the middle part up to 74m acidic formations and > 74m massive and fractured basalt, which is may be described as the upper aquifer. In this area, the northwestern part is acts as a recharge area and the southeastern part as a discharge area. As can be seen from the hydrogeological cross-section, the groundwater flow system is from the northwest to southeast direction.

In Sayit wereda, the collected data shows that the wells discharge are ranging from 0.1 to 8 l/s with a maximum depth of 77m. Generally, depth to water level decreases (comes up) from east to west direction. The lithological log of these boreholes of the area generally shows that, on the top part (0 - 5) meters depth soft formations and > 5m weathered and fractured basalt, which is may be described as the upper aquifer. In general, in this area, the eastern part is acts as a recharge area and the western part as a discharge area. As can be seen from the hydrogeological x-sections, the groundwater flow system in this area is from east to west, west to east, and north to south directions.

Geology and hydrogeology of the study areas have been used to construct a conceptual model for groundwater recharge, occurrence, and flow. Therefore, the conceptual model of these areas is presented in Figures 18, 19, 20, and 21 below

3.14 Hydrogeological condition of Cluster 4

The study areas fall in the upper Tekeze basin. The hydrogeological conditions of the area depend on the geology, geologic structures, and geomorphology of the area. The geology of the study areas is mainly Consolidated and unconsolidated sediment and basic volcanic rocks covered by thin soil, pyroclastic, trachyte, and basalt are the main volcanic rocks of the study area. They are jointed, fractured, and affected by dense weathering.

Geomorphologically the study areas are rugged. According to previous studies and hydrogeological set up of the study areas, the major sources of recharge for the study areas (Weredas) are:

- precipitation induced within the study areas
- Infiltration from surface rivers and overland flows

In addition, geomorphological setup, water level observed, geologic structures, groundwater contour, and conceptual model developed in previous studies shows that groundwater recharged at central and northern highland areas flow toward Tekeze gorge and mixed up with groundwater recharge from surface rivers and rainfall-induced in the area and heads northward.

The hydrogeological setup of each areas (Weredas) is discussed as follows:

Misrak Belesa and Ebenat

The Tertiary volcanic rocks in the study area are fractured and jointed. Numerous good discharge springs emerge along with the fractures and contacts. This is due to that the plateaus have high precipitation, infiltration, storage, and low evapotranspiration. Few water points at Mesozoic sandstone and sediments are inventoried having lower yields and quality that drain highland volcanic rocks. Structurally affected Tana graben and lacustrine sediments of the Tana graben area are highly productive for groundwater resource development. On the other hand, valleys along the extended fractures of the river channels that have a thick succession of alluvial deposits have also good groundwater resource regions. They have recharge from rainfall, groundwater base flow, and direct runoff.

The groundwater flow direction is determined using water level data available for existing boreholes, dug wells, and springs. Groundwater flow is discussed here on the basis of topography, geology, and structures.

Topographically, much like the flow of water in a river, the flow of groundwater is subjected to gravity and is almost always in motion, flowing from areas of higher elevation to areas of lower elevation. Groundwater appears at the surface in the form of springs under the plateaus and as dug wells at the stream valleys. The boreholes are shallow. Generally, groundwater flow in the area can be indicated from the northern and southern highlands to the central Tekeze gorge.

Most of the study area rivers are oriented in the direction of the E-W extended fractures and flow towards Tekeze gorge, and the groundwater follows these paths. These fractures control the movements of groundwater in the alluvial deposits.

Lithologically, groundwater flow in the hard rock is through fractured zones and the weathered mantle called overburden or regolith. Groundwater flow in the Tertiary volcanic rock and in the

sedimentary sandstone can be horizontal along with the bedding and/or can be vertical along with the vertical fractures. The outlet springs can indicate the general groundwater flow direction in the Tertiary volcanic rock.

As depicted on the hydrogeological map and also cross-section constructed along the groundwater flow path to conceptualize groundwater flow and storage in this wereda (Figure 22, 23, 24 & 25) and also stated in previous works, the Tertiary volcanic units are recharged directly from precipitation, perennial rivers, and runoff and groundwater flow. However, the Tekeze river gorge and lithological units along with the gorges, Mesozoic sediments of lower sandstone have low rainfall and increased potential evapotranspiration with low recharge from rainfall infiltration. The low drainage density, low precipitation, and productivity of the wells in the metamorphic formations indicate that considerable recharge occurs from groundwater flow and perennial rivers. High precipitation and an increase in spring discharge during the rainy season in the volcanic rocks indicate recharge occurs from rainfall infiltration. On the other hand, the lacustrine sediments obtain recharge from rainfall, groundwater base flow, and direct runoff.

From a hydrogeological point of view, most areas of these weredas exposures are favorable for groundwater recharge, storage, and movement due to the existence of primary and secondary porosities..

Bugna and Meket

From a geomorphological point of view, the groundwater may follow the surface drainage system. The topography of the area generally slopes towards the west and northwest. Topographically, much like the flow of water in a river, the flow of groundwater is subjected to gravity, flowing from areas of higher elevation to areas of lower elevation. Groundwater appears at the surface in the form of springs under the plateaus and as dug wells at the stream valleys at some part of Meket wereda and the boreholes are shallow. Generally, groundwater flow in the area can be indicated from the Eastern and southern highlands to the central Tekeze gorge.

In shallow groundwater, the movement and flow direction are dependent on the inclination, steepness, or slope of the topography in the area. The direction of flow of springs controlled by topographic breaks is an indicator of the possible groundwater flow. As shown on the hydrogeological map and on cross-section constructed along the groundwater flow path to conceptualize groundwater flow and storage in these weredas (Figure 26, 27, 28 and 29) and also stated in previous works, the Tertiary volcanic units are recharged directly from precipitation, perennial rivers, and runoff. The groundwater flows from the southern mountain chain to the north and northwest. Existing data generally show groundwater flow to the northwest.

Tselemit Wereda

The geology of the area is mainly tertiary trap volcanics consisting of black olivine alkali basalt flows. It is coarse, intergranular texture has well-developed columnar jointing, and has concentrations of white zeolite and inter-flow fossil soils. Inter bedded lacustrine deposits of white silicified limestone and diatomite with gastropods occur at several levels.

The hydrogeological setup of the area shows that, the major sources of recharge for the study area (Tselemit Wereda) is deemed to be from Ras-Dashen Mountain composed of mainly tertiary trap volcanic to the northeastern direction toward Tekeze gorge through fractured, dissected intermountain valleys of erosional effects and jointed tertiary basalts.

In addition, geomorphological setup, geologic structures, NE river orientations in the Tselemit wereda shows that the groundwater recharged on the highland areas of Ras-Dashen Mountain is anticipated to get the highest annual rainfall and flows toward the Tekeze river gorge. According to the preliminary hydrogeological map of the area depicted below the study, wereda is found mainly within the extensive and moderately productive fissured aquifers of the tertiary trap basalts (Figure 30 and 31).

4. RESULT AND DISCUSSION

4.1 Multi-criteria decision analysis (MCDA) Weight assignment using AHP of each wereda

Five information layers (Lithology, Recharge, TWI, Lineament density, and Lineament proximity) that determine the groundwater potential are selected for all weredas, and weights are determined based on conceptual groundwater system for each weredas separately.

The weighting criterias are prepared by AHP (Analytic Hierarch process) (EVM multiple inputs) (K.D. Version 15.09.2018) based on the conceptual model and thematic layers proposed to use. As the hydrogeological conditions vary greatly across the projects, weights were determined for each Wereda separately (See Table 25 to 43). The minimum and maximum values are included as well, which will be taken as the basis for sensitivity analyses on the mapped groundwater potential zones.

Analytic Hierarchy Process

The first step of the AHP method is to assign the level of importance of each factor based on Saaty's (2008) scale values. Consequently, all factors are compared in a pairwise comparison matrix. The weight which was assigned to different thematic layers was normalized using Saaty's AHP techniques. To control and test the Consistency Ratio (CR) is calculated. The first step to calculate CR is to compute the maximum eigenvalue (λ_{max}). Then, calculate the consistency Index (CI) using equation 5, where n is a number of factors. CR is resulted by dividing CI by RI (ratio Index). The value of RI is given based on Saaty's 1 – 9. If the value is less than 0.1, the judgment of weights is acceptable and consistent. If CR is greater than 10%, we need to revise the subjective judgment.

$$CI = \frac{\lambda_{max} - n}{n - 1} \text{-----Eq.5}$$

Consistency Ratio = Consistency Index /Random Index

$$CR = \frac{CI}{RI} \text{-----E.q.6}$$

Table 23: Random Index

| Attribute | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-----------|------|------|------|------|------|-----|------|------|

4.2 Reclassification of Thematic layers

4.2.1 Hydro - lithologic units

Hydrogeological units play a fundamental role in governing the spatial distribution and occurrence of groundwater. The porosity, size of pore space, and the ease at which the pore spaces are interconnected control storage and permeability of geologic medium that in turn affect the availability of groundwater in the area of interest. The main lithologic units found in the study area consist of Elluvium& alluvial sediments, Aiba basalt, Tarmaber-Megezez basalt, Ignimbrite, Adigrat sandstone, Gohatsion formation, and Antalo limestone. These lithologic units have been given weights (rates) based on hydraulic properties (hydraulic conductivity, transmissivity, Storativity and yields observed from pumping test, lithologic log (well completion reports) of the area. Based on the conceptual understanding of the project weredas, the Hydrogeological units of the project weredas were classified as very high, high, moderate, low, and very low potential. The reclassified hydrogeological units are presented in figures 32 to 45 below.

4.2.2 Groundwater Recharge

Groundwater recharge of Awash basin (upstream Cluster 1 weredas), Abay basin (upstream of cluster 2 & 3 Weredas), and Tekeze basin (upstream of cluster 4 & Tselemit wereda) were estimated by using the WetSpass model, and then groundwater recharge of the study areas were extracted by respective weredas boundary.

The WetSpass model produces monthly hydrological parameters like grid maps of groundwater recharge, actual evapotranspiration, surface runoff, interception loss, evaporation, etc. In this study, the annual groundwater recharge, annual actual evapotranspiration, and annual surface runoff are calculated from monthly recharge, actual evapotranspiration, and surface runoff by using a raster calculator of ARC GIS 10.8 respectively. A brief description of this output will be presented as a separate document in the phase III water balance study report.

There are different models to estimate recharge in a given area depending on actual areal conditions. In this case, the WetSpass model estimates monthly long-term spatial distribution amounts of groundwater recharge of Awash, Abay, and Tekeze basins by subtracting the monthly surface runoff, Interception, and evapotranspiration from the monthly precipitation.

Usually, the recharge areas are in topographic high places; discharge areas are located in topographic low. Using only a topographic setup of the area could not be enough to classify the area as recharge and discharge zones. Land use/land cover, soil types, and morphology of land are equally important in the classification of the area into recharge and discharge zones.

Since recharge is a result of evapotranspiration and surface runoff processes it incorporates all influences and spatial patterns of these processes.

Figures 46 to 59 show the yearly groundwater recharge estimated with the WetSpass model of each project weredas. The recharge estimated was used as one thematic layer for groundwater potential mapping of the project weredas. The values were reclassified into five categories or classes such as very low, low, moderate, high, and very high by using the natural break classification method. The high weights have been assigned for high groundwater recharge areas and vice versa.

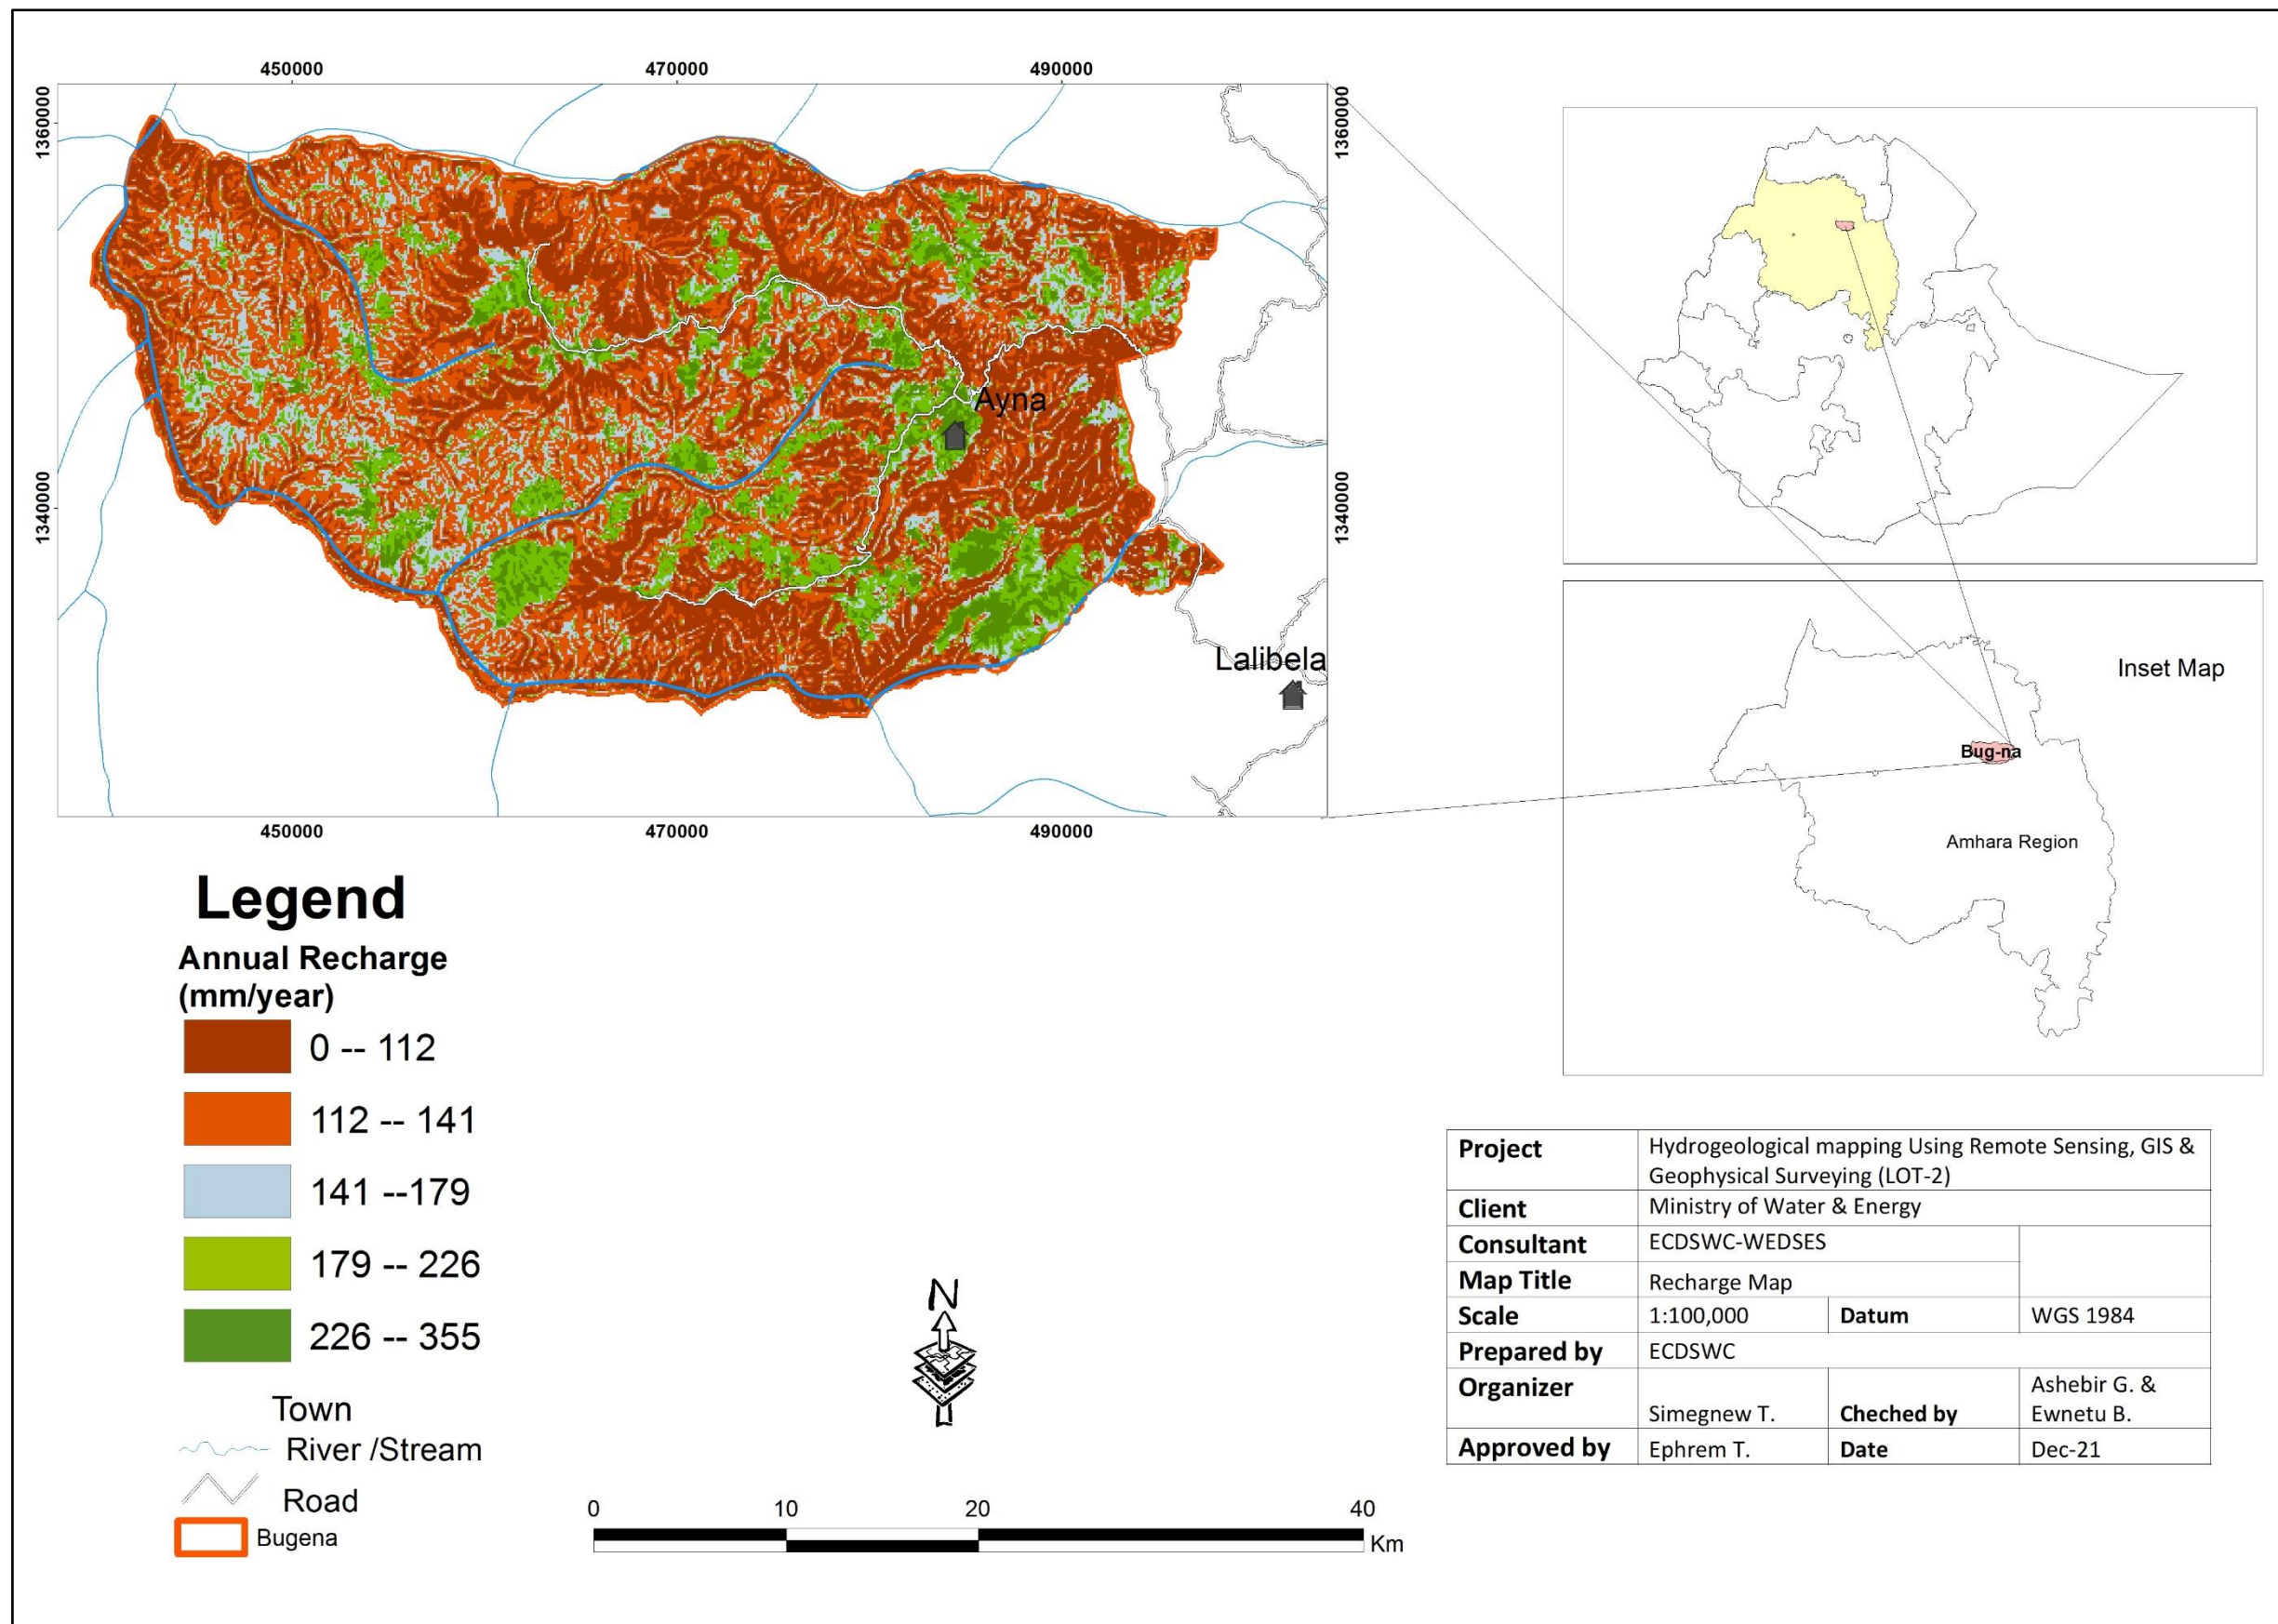

Figure 58 Groundwater recharge of Bugna Wereda

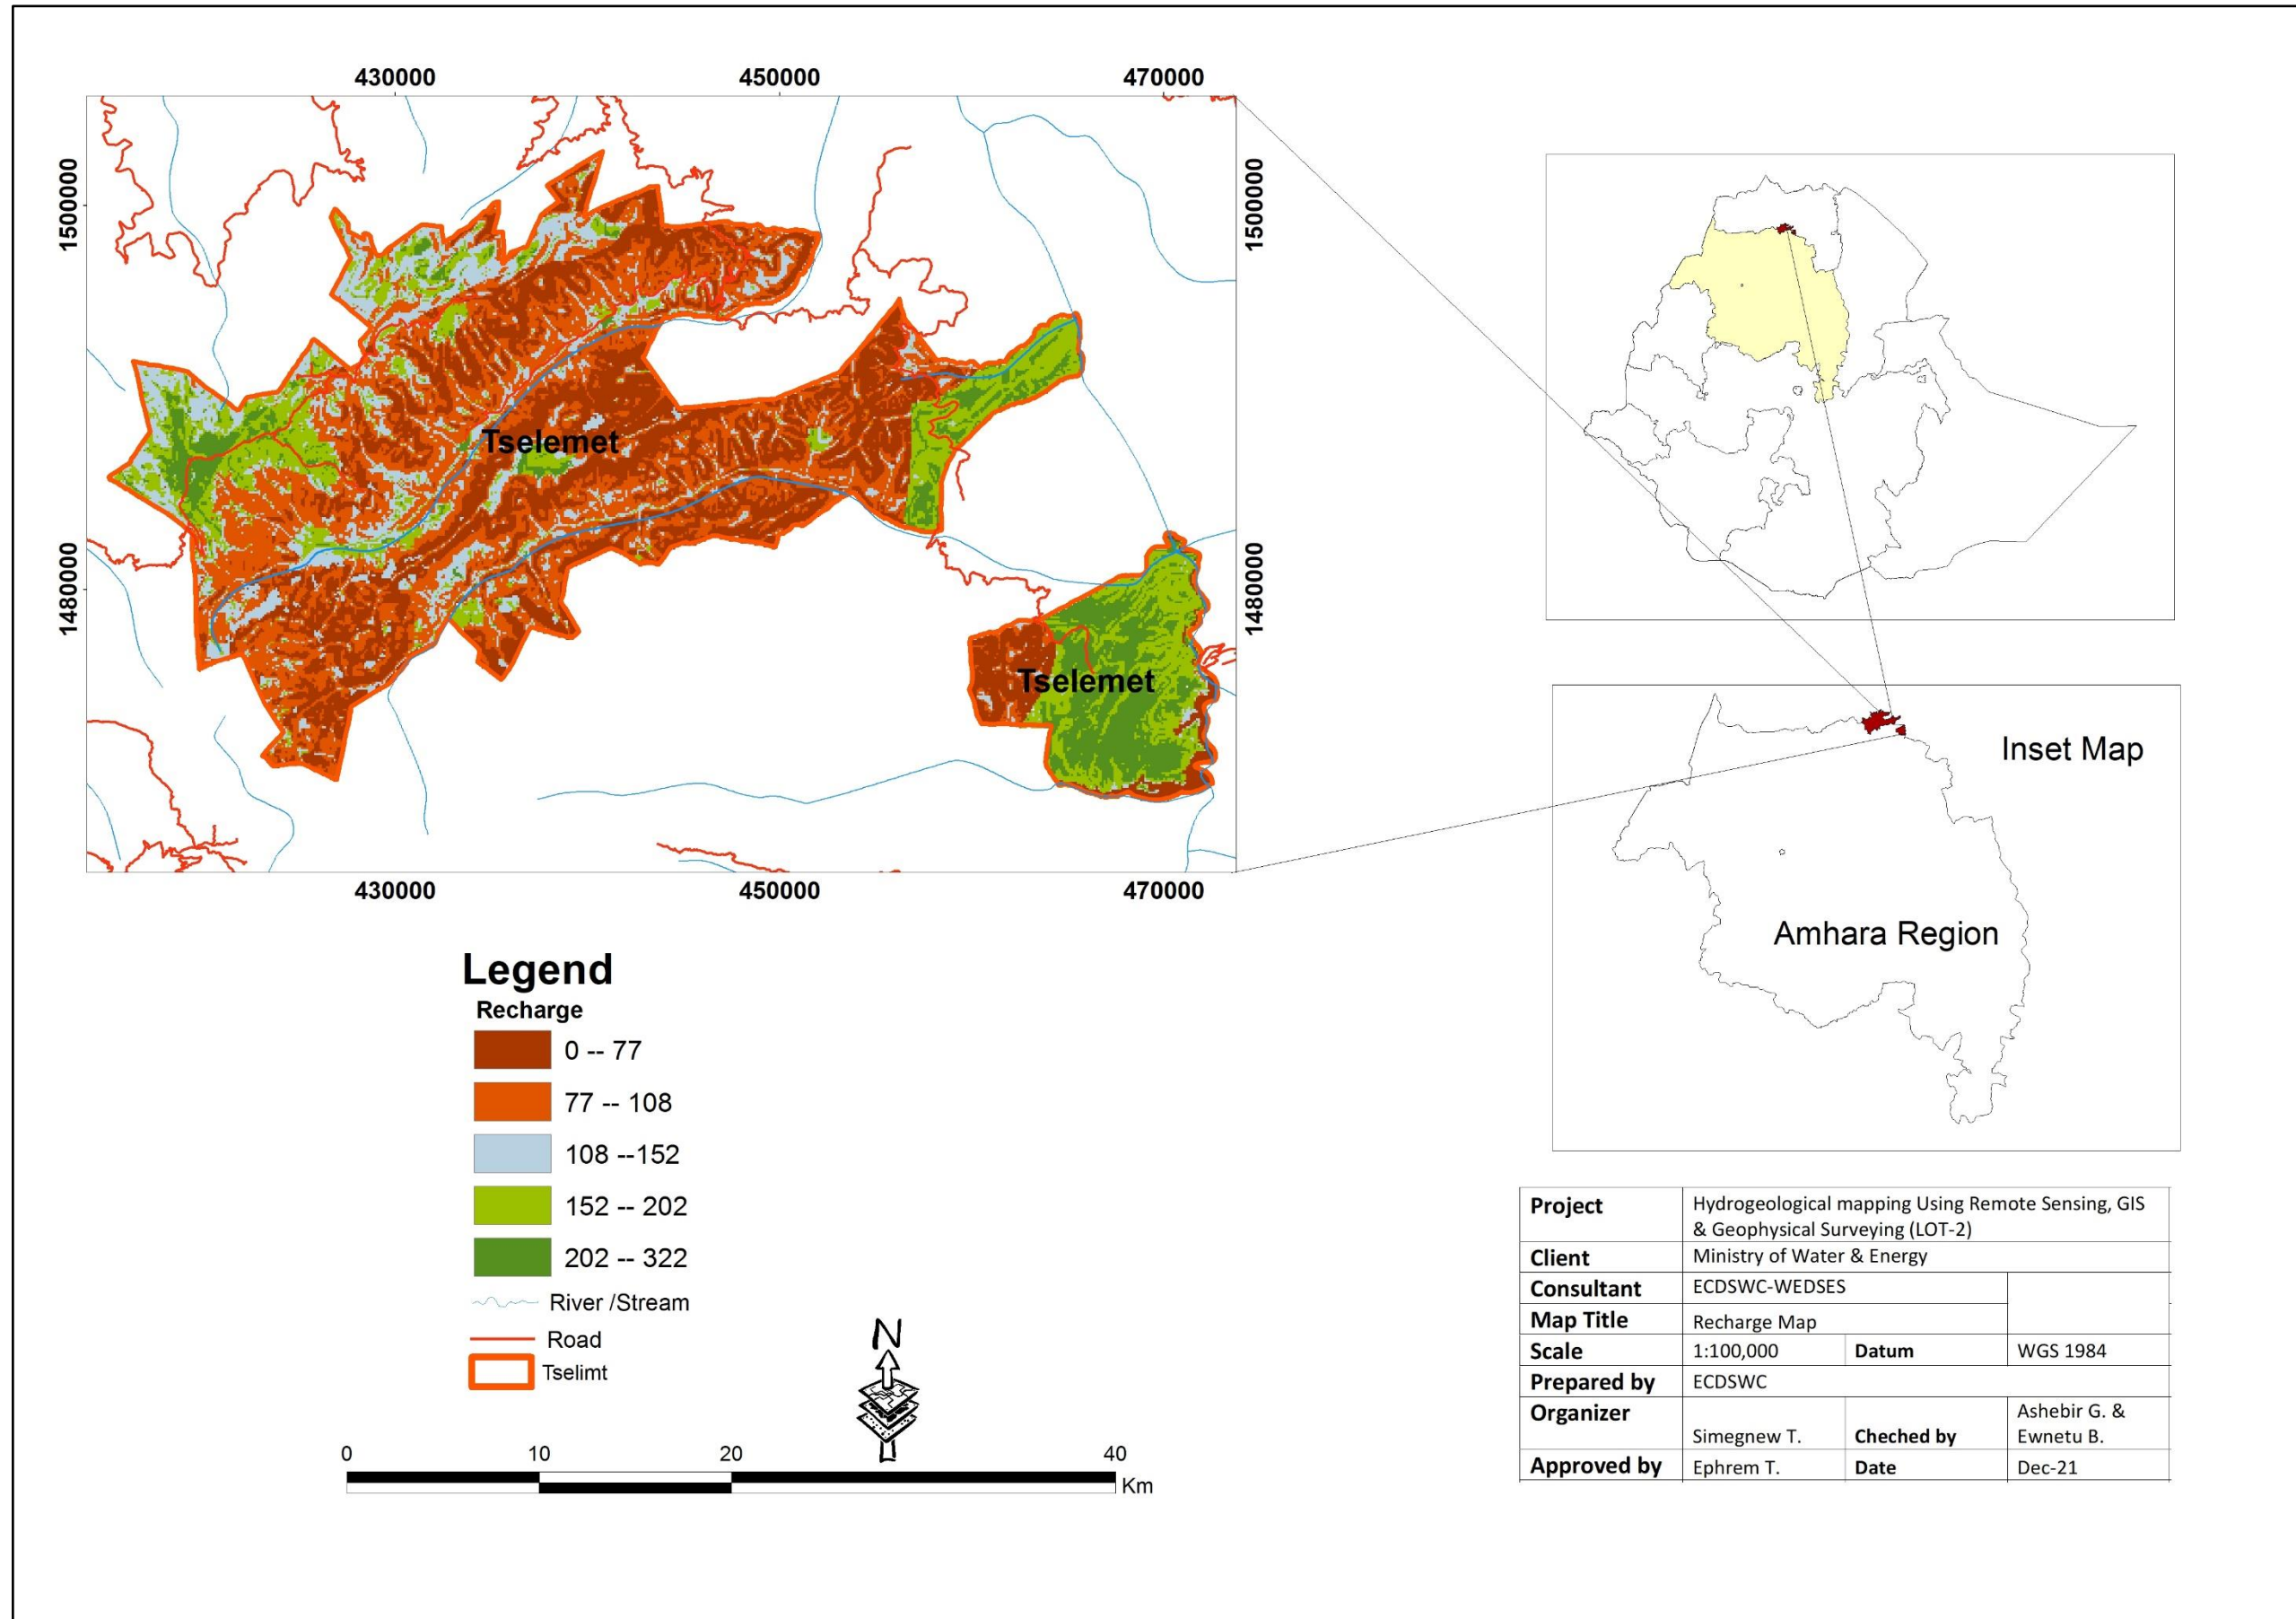

Figure 59: Groundwater recharge of Tselemit Wereda

4.2.3 TWI

Topographic Wetness Index (TWI) is used to compute topographic control on the hydrological process and reflects the potential groundwater infiltration caused by the effect of topography. The values were reclassified into five categories such as very low, low, moderate, high, and very high. The high weights have been assigned for high TWI and vice versa. Figure 60 - 73 shows the TWI maps of the project weredas.

4.2.4 Lineament Density

Like primary porosity, secondary porosity is also essential for the determination of hydrogeological conditions. Lineaments represent secondary porosity and are linear features of tectonic origin. Due to their linear, direct, curvilinear form, they can easily be demarcated in satellite imagery. Some other indications like tone, texture, relief, drainage, and vegetation soil tone's linearity also give valuable information for lineament differentiation.

The groundwater potential is expected to increase with increasing lineament density values. Thus, areas that are characterized by high lineament density values are expected to have high groundwater potential. This is because; lineament acts as conduits for groundwater flow and reservoir for groundwater storage .considering lineament map as a baseline, lineament density is defined as the total length of the lineament per unit area.

The lineament density of the project weredas was classified into five classes, in decreasing order of their relative infiltration capability. These classes were: 5, 4, 3, 2, and 1, representing very high, high, medium, low, and very low density, respectively (figure 74 to 87)

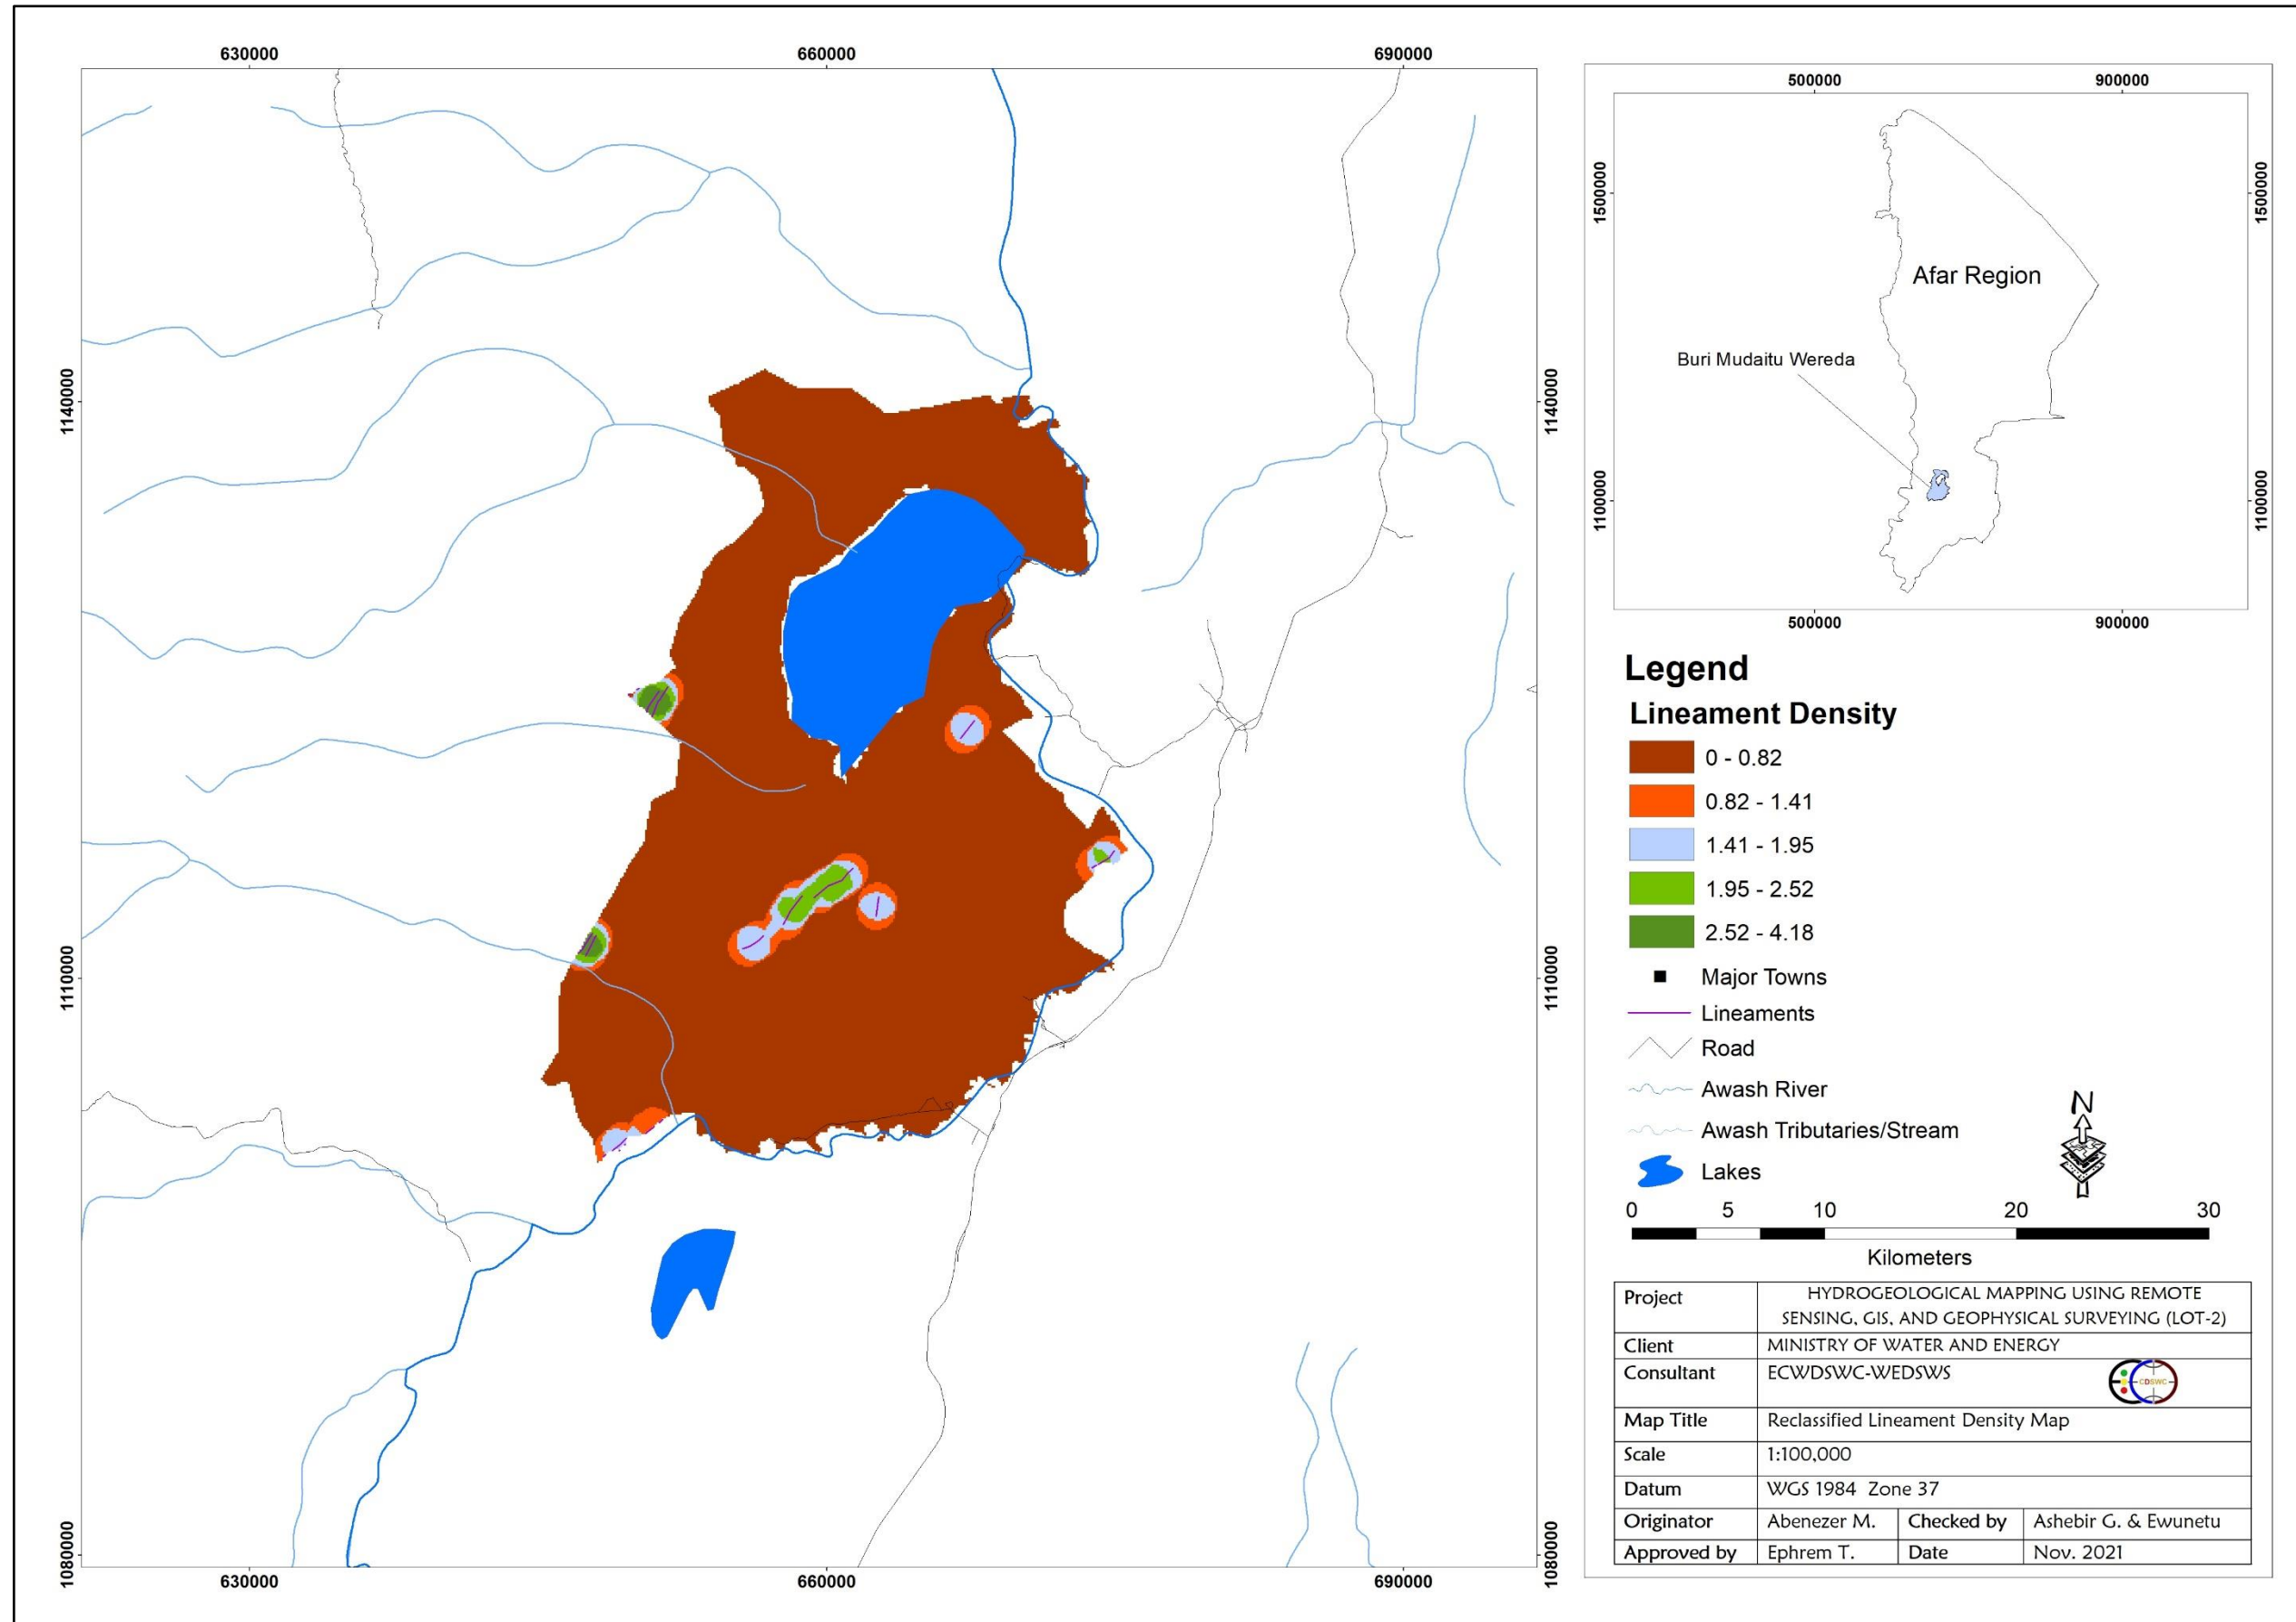

Figure 74: Lineament Density map of Buri Mudaitu Wereda

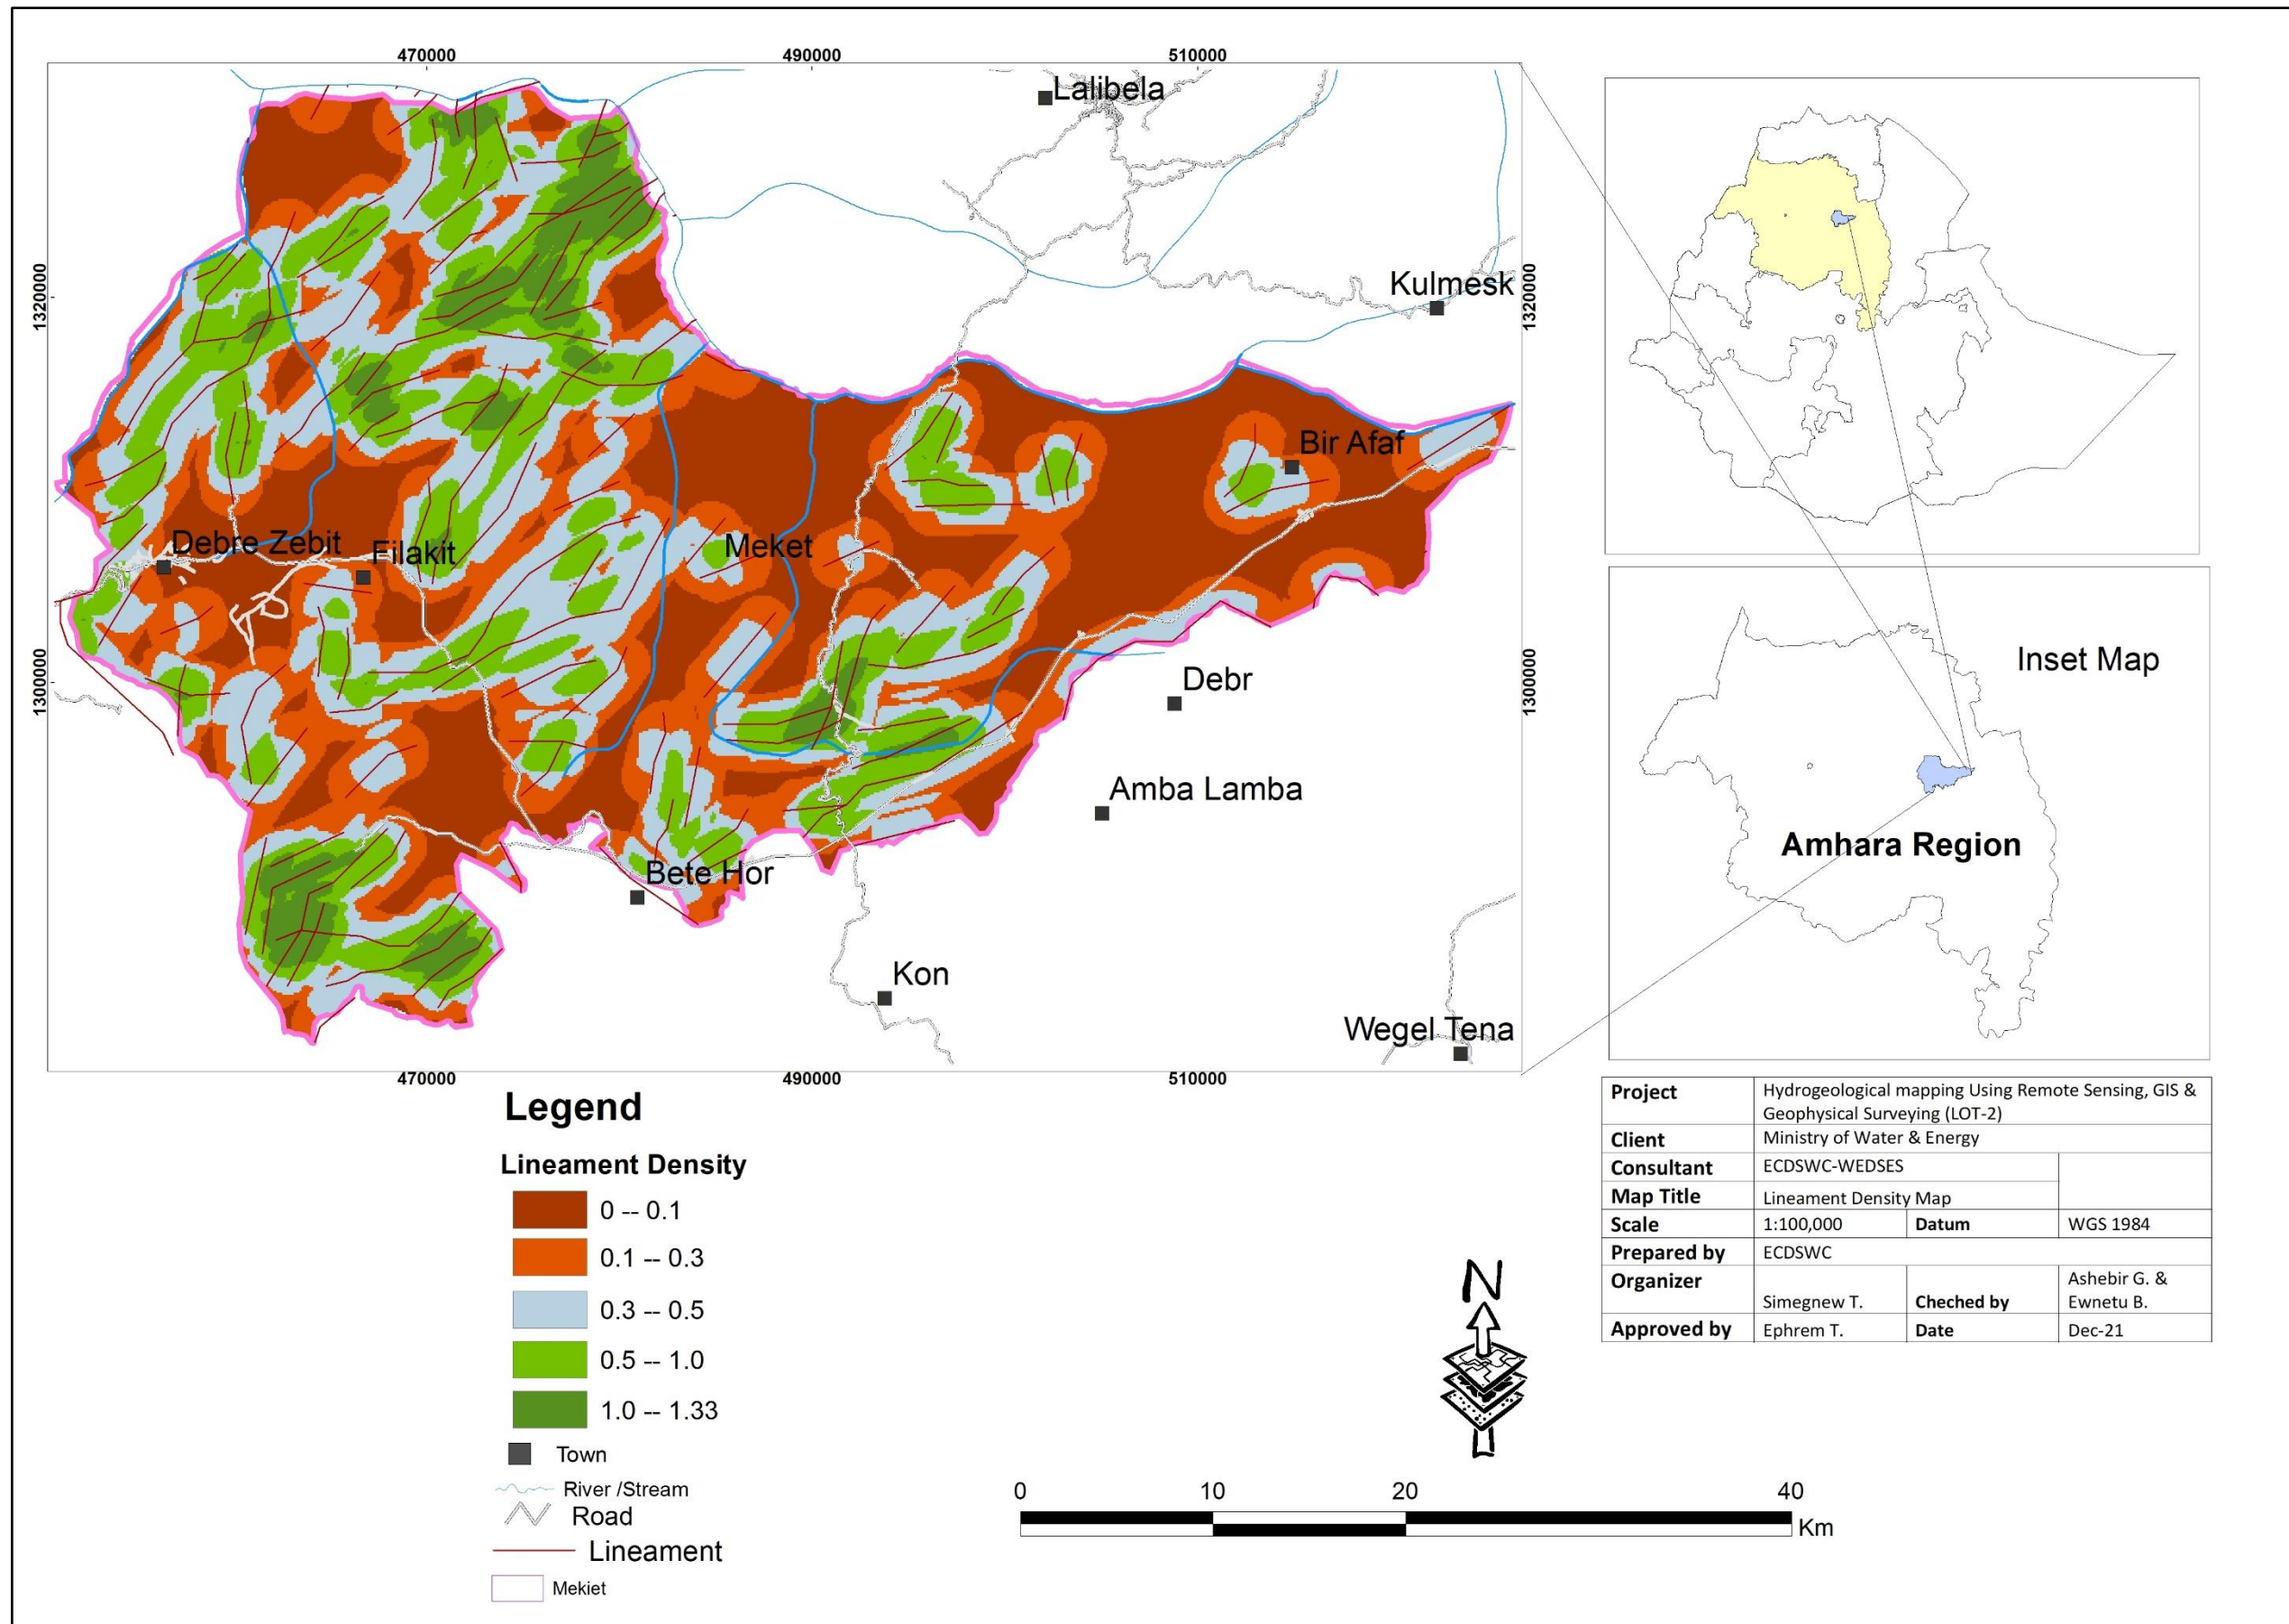

Figure 85: Lineament Density map of Mekiet Wereda

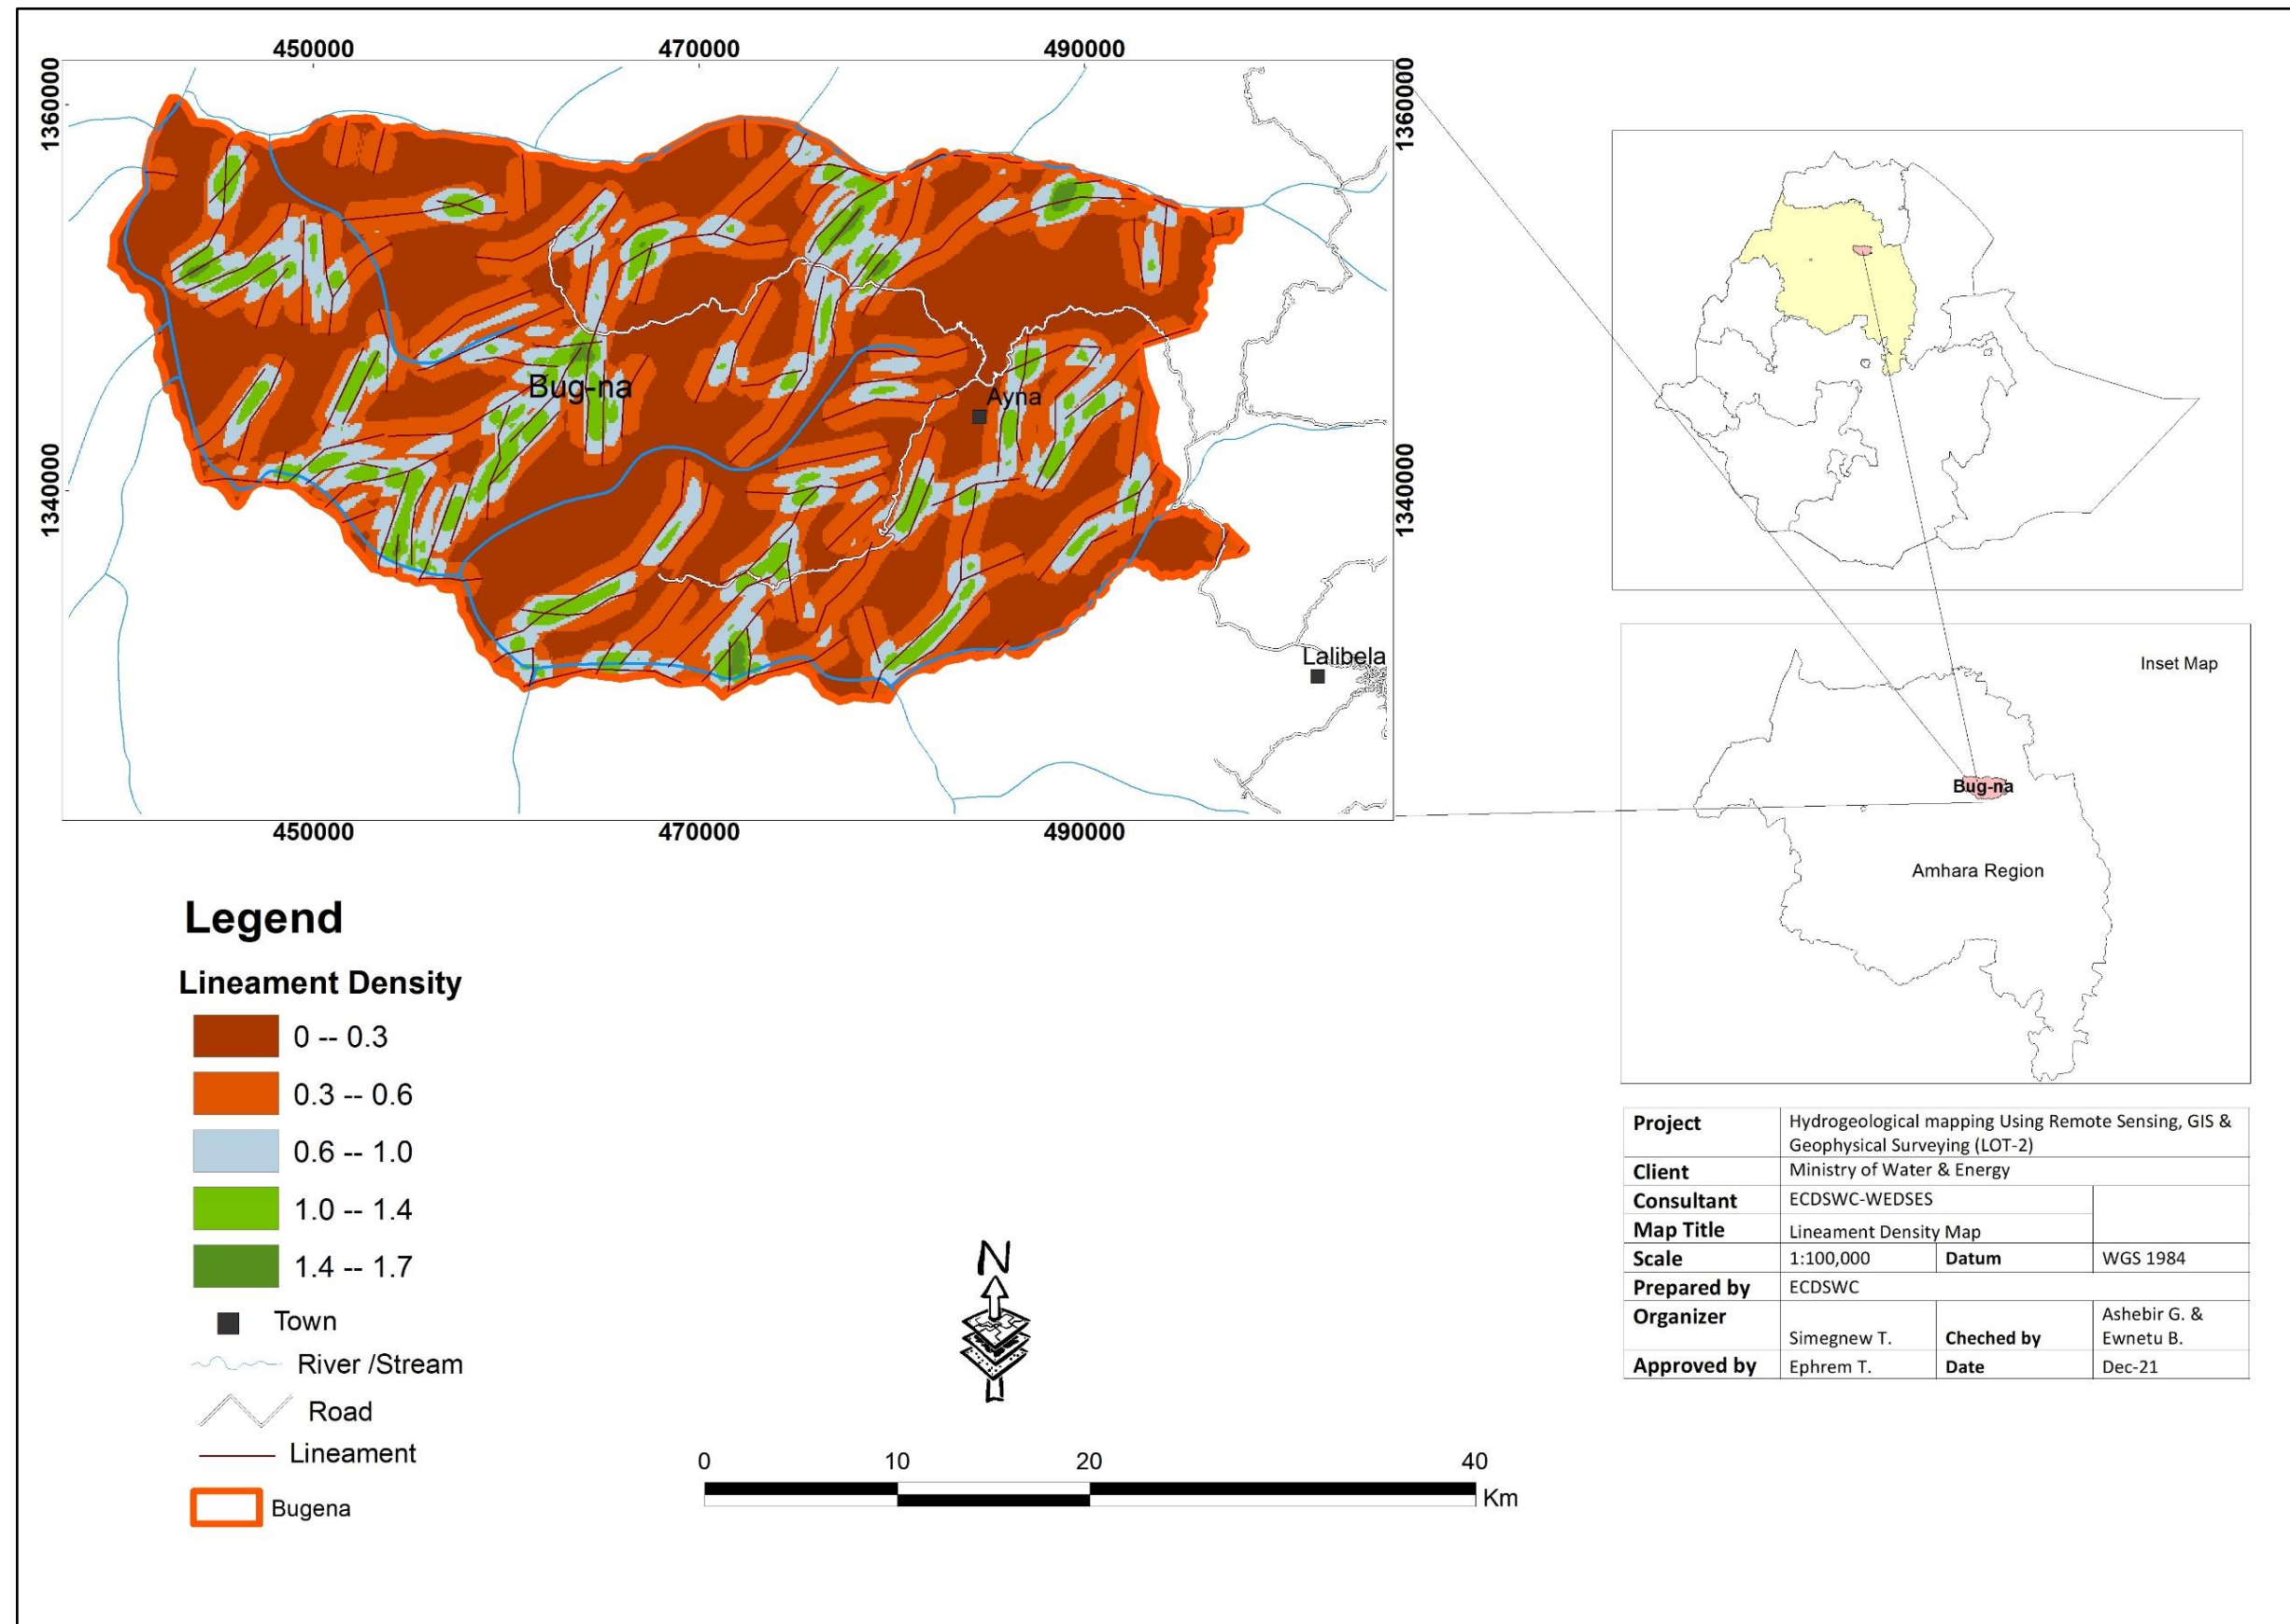

Figure 86: Lineament Density map of Bugna Wereda

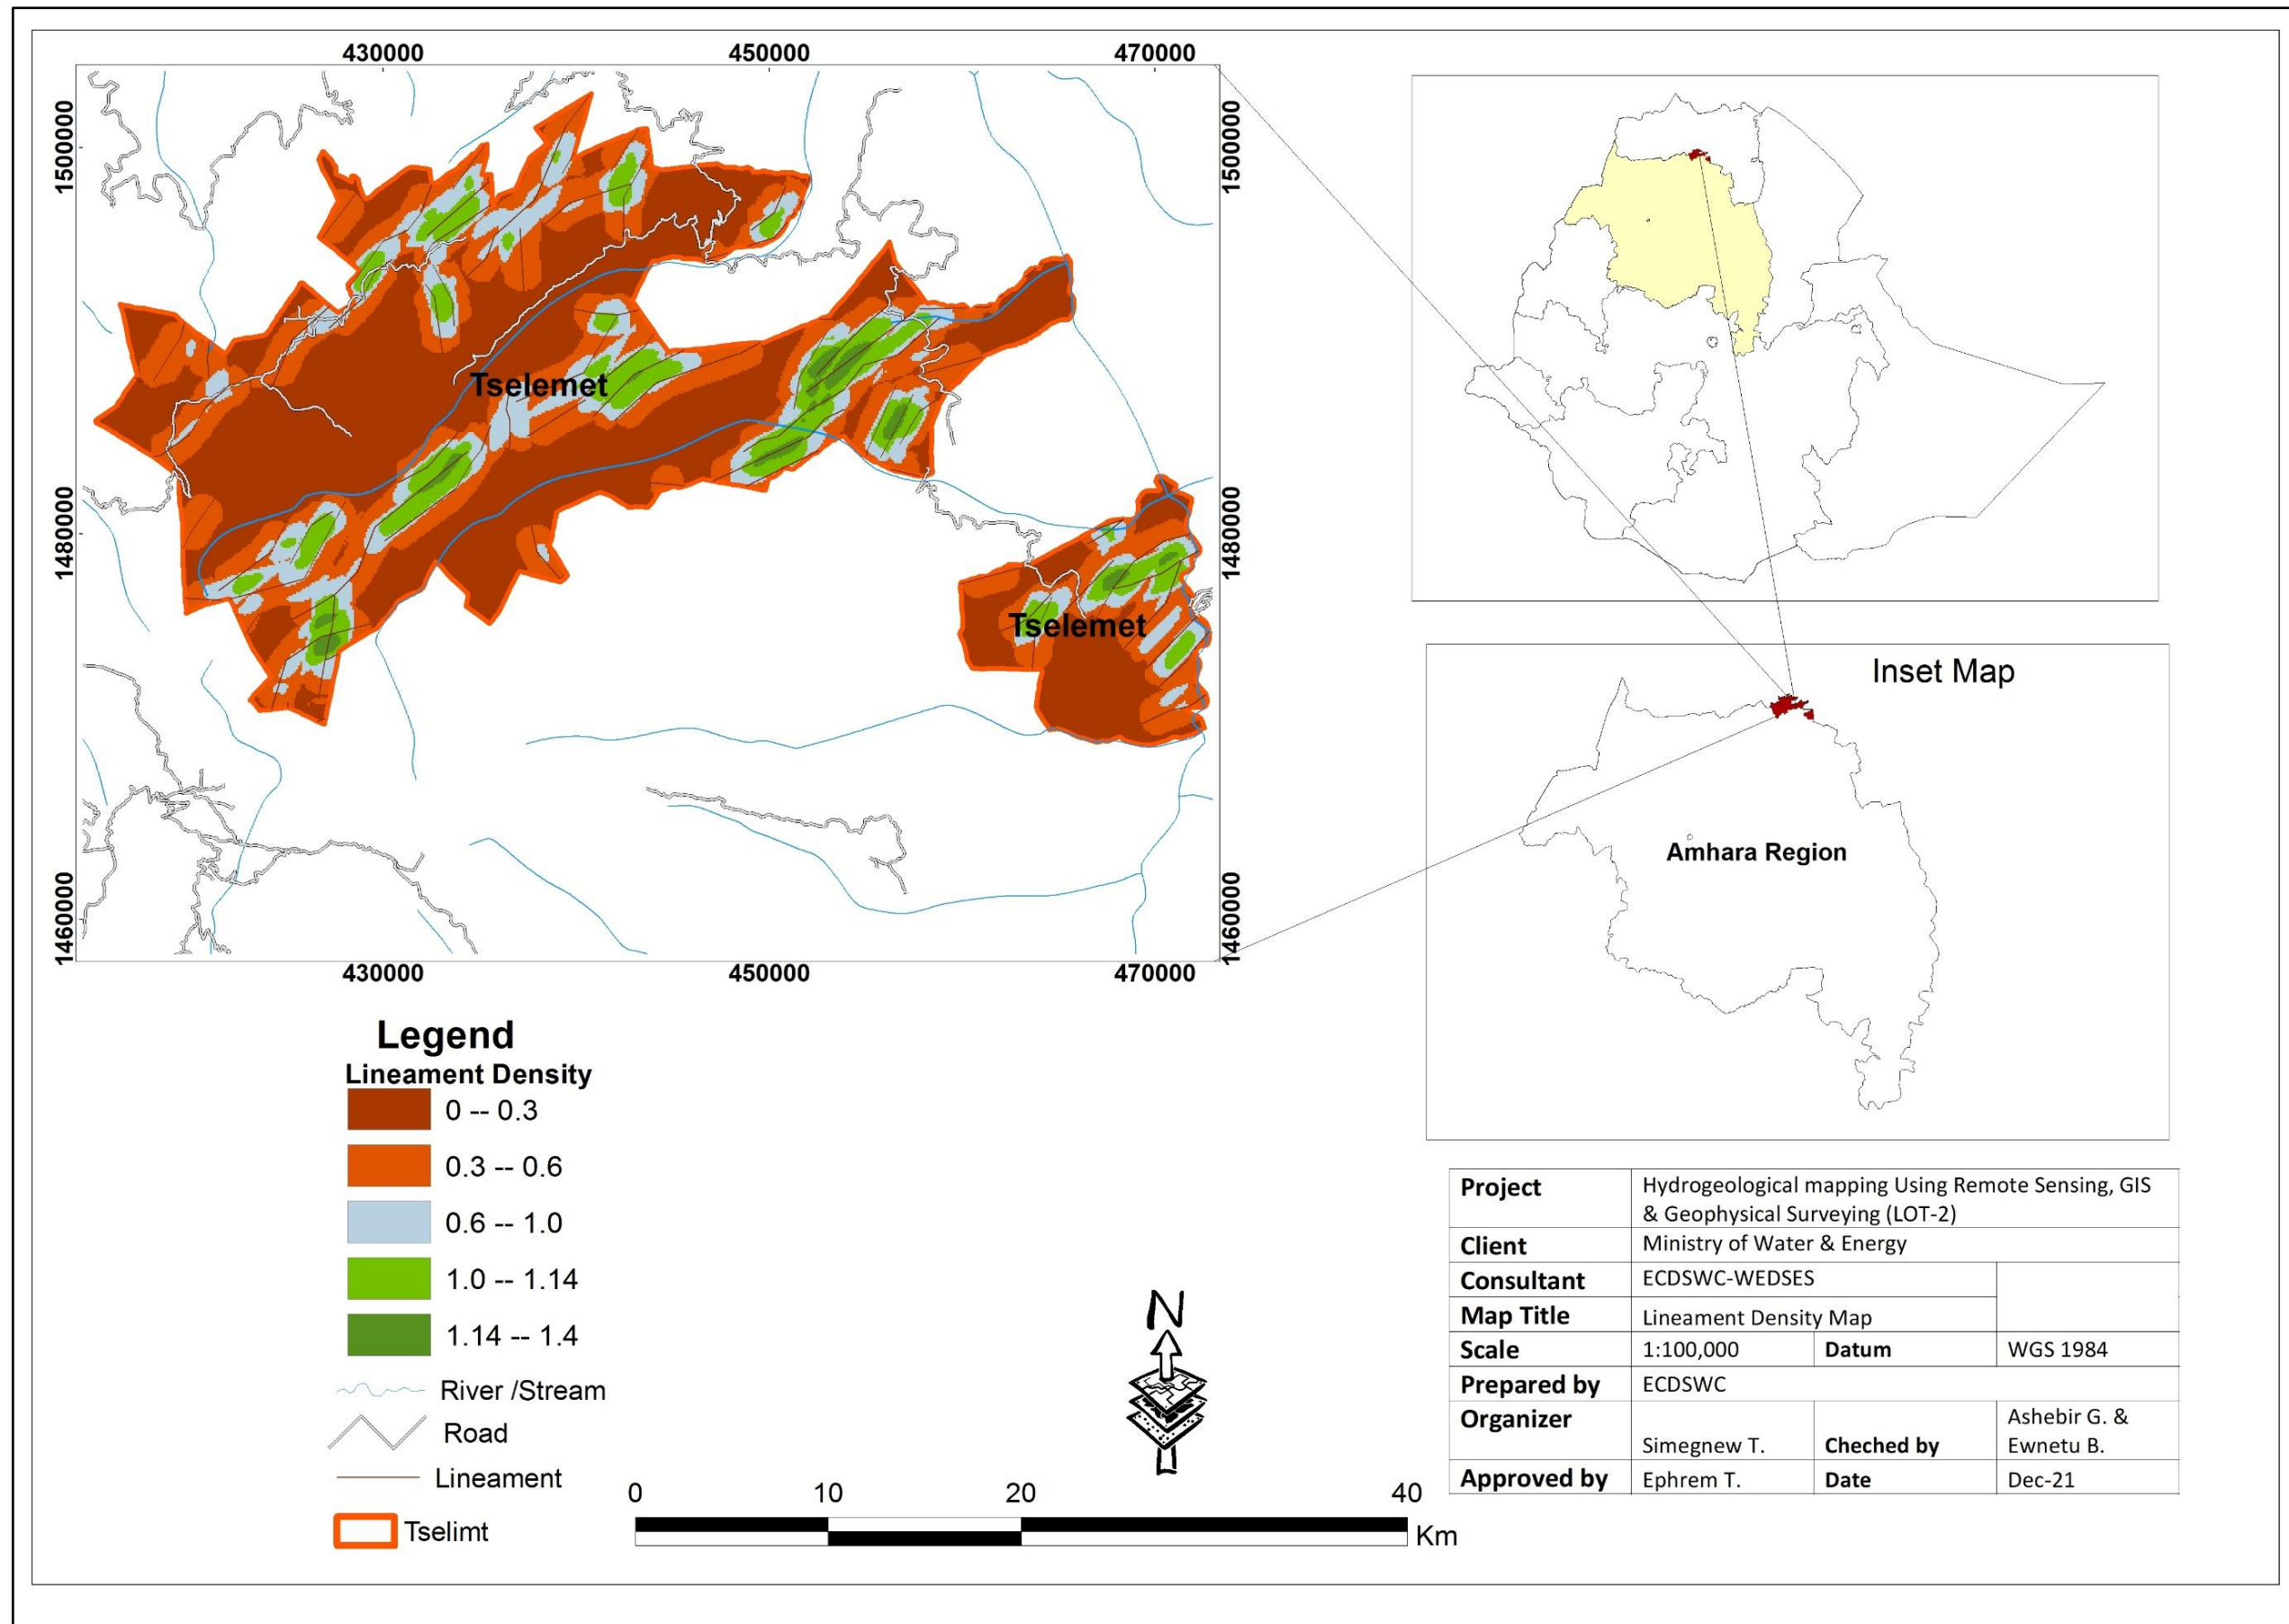

Figure 87: Lineament Density map of Tselemit Wereda

4.2.5 Lineament Proximity thematic layers

There is a close relationship between lineament proximity and groundwater potential. Thus, the intensity of groundwater potential decreases with increasing distance from the lineaments and increases with decreasing distance from the lineament. The proximity from the lineament was derived by creating buffers based on conceptual understanding of the specific project weredas. High weights are assigned to the areas nearby the lineament and low weights to distance locations. The proximity from lineament maps is shown in figures (88 to 101).

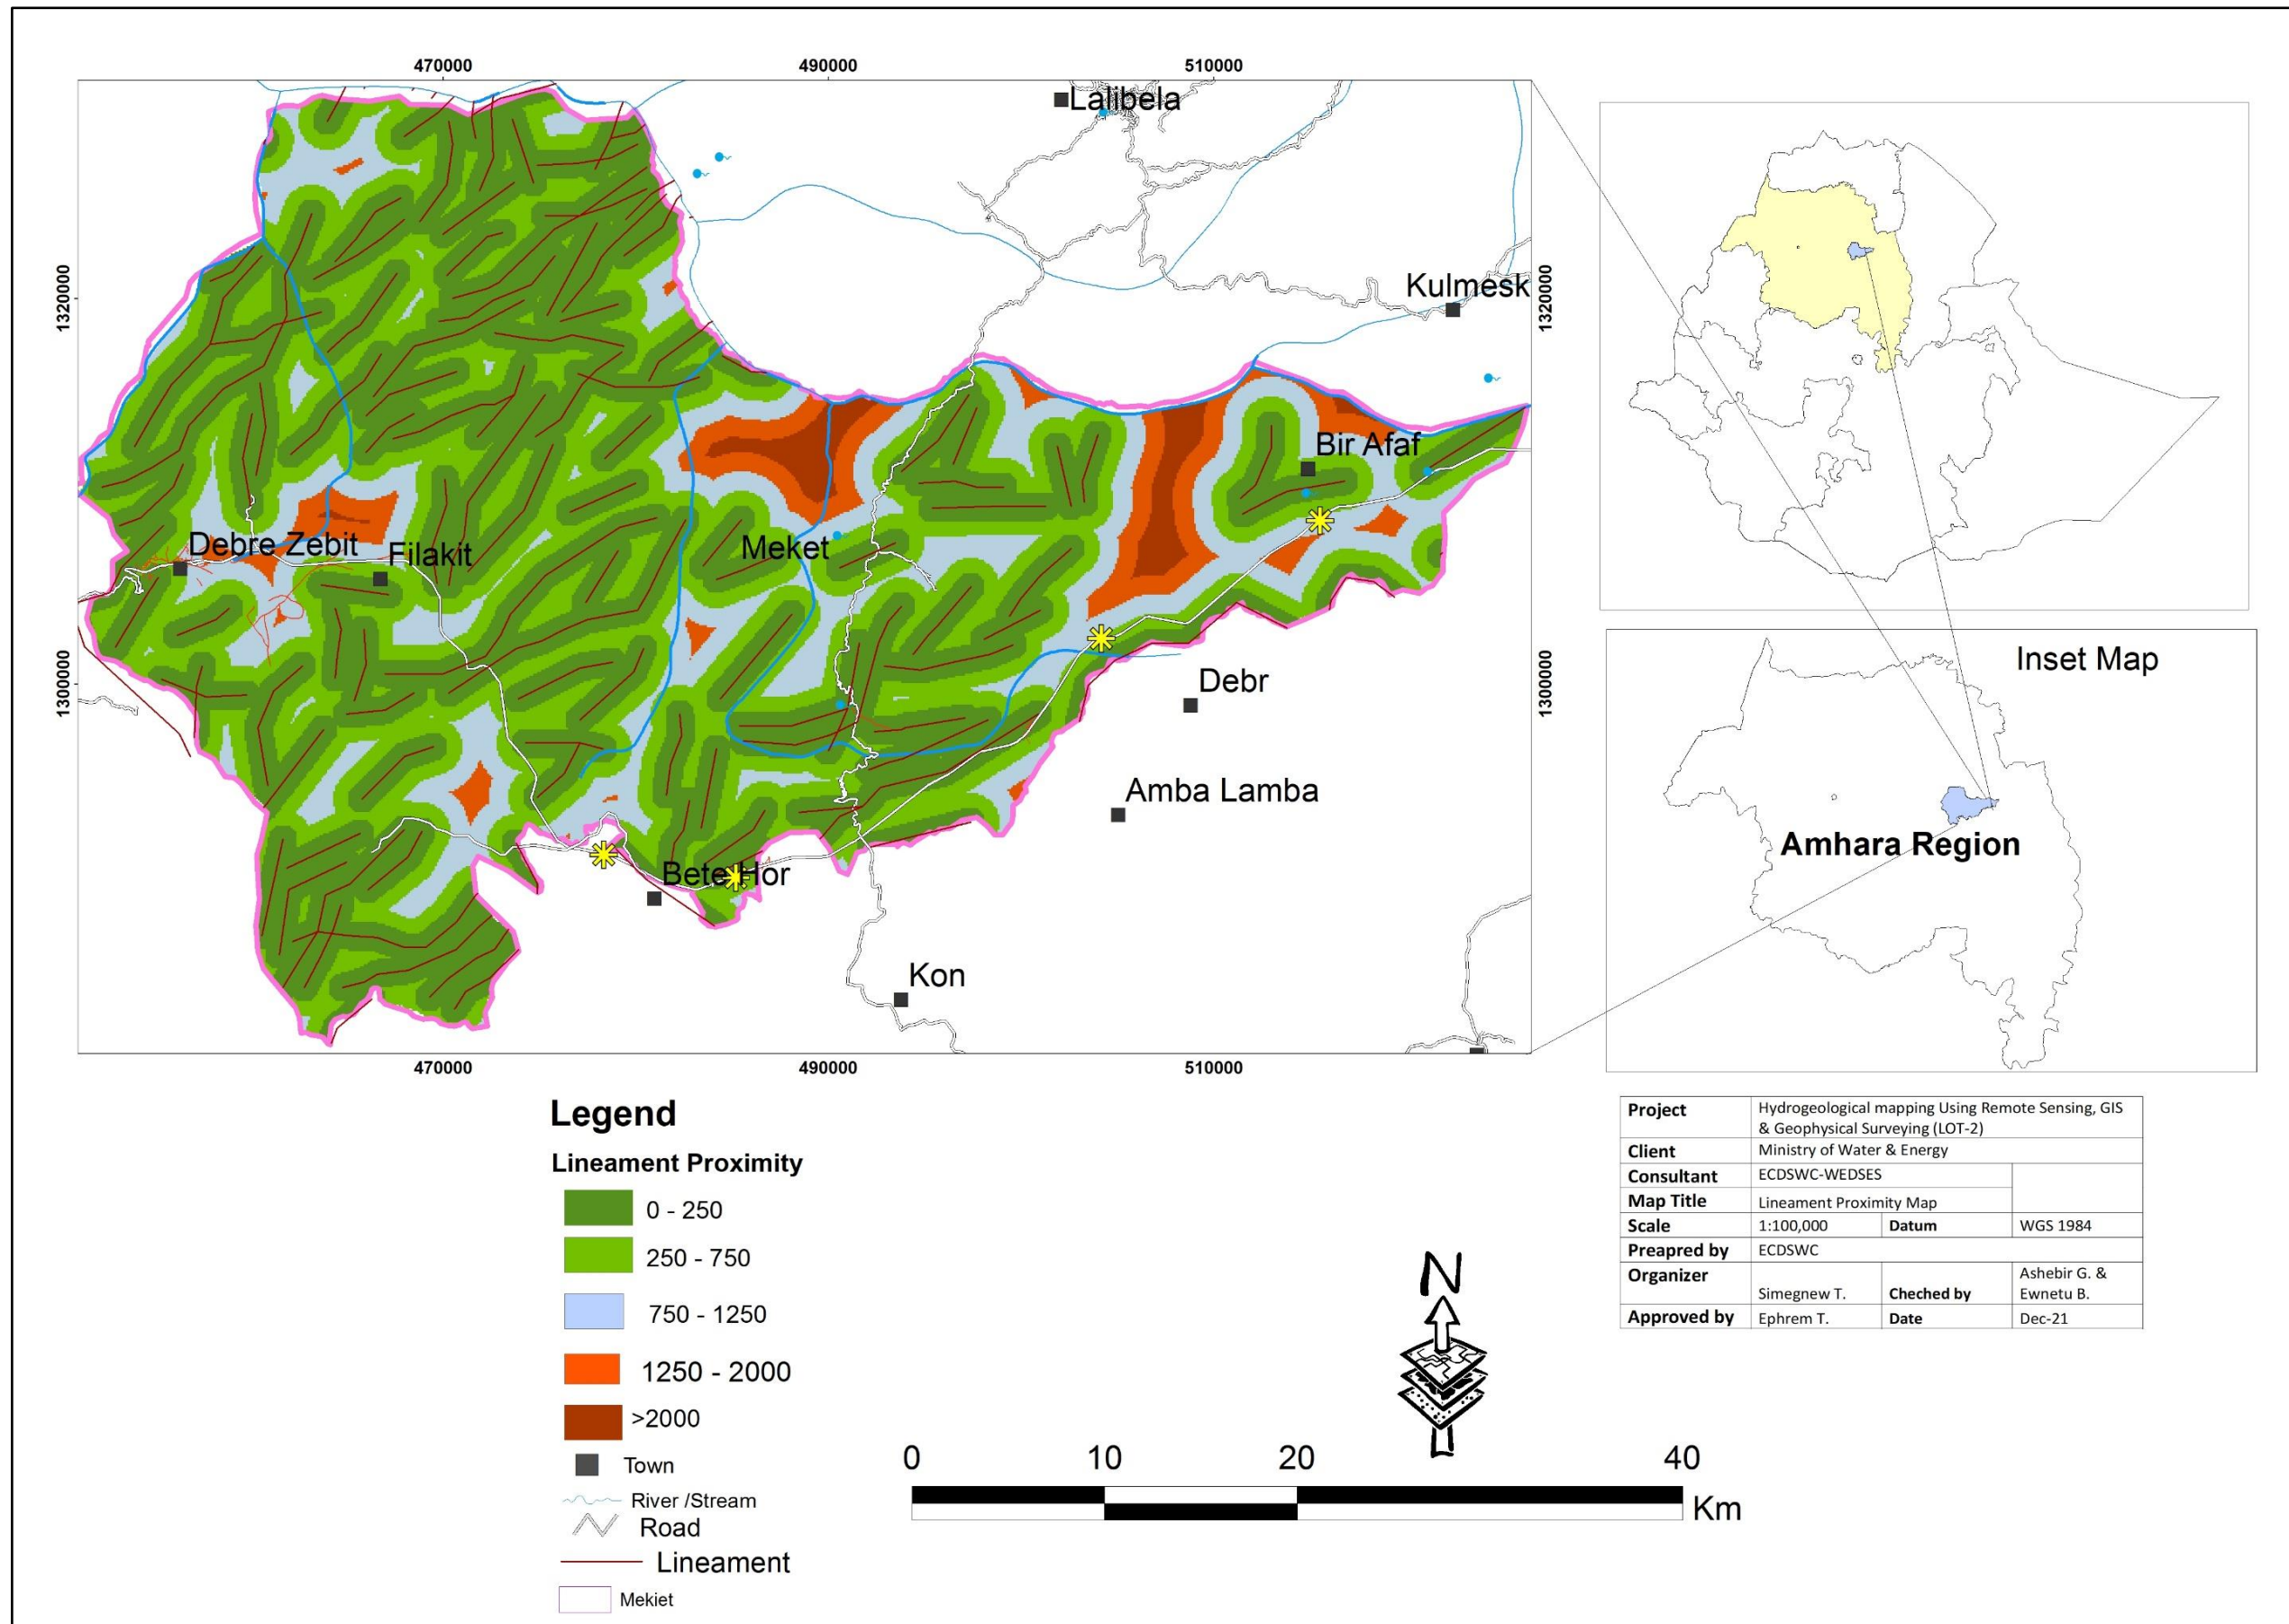

Figure 99: Lineament Proximity Map of Mekiet Wereda

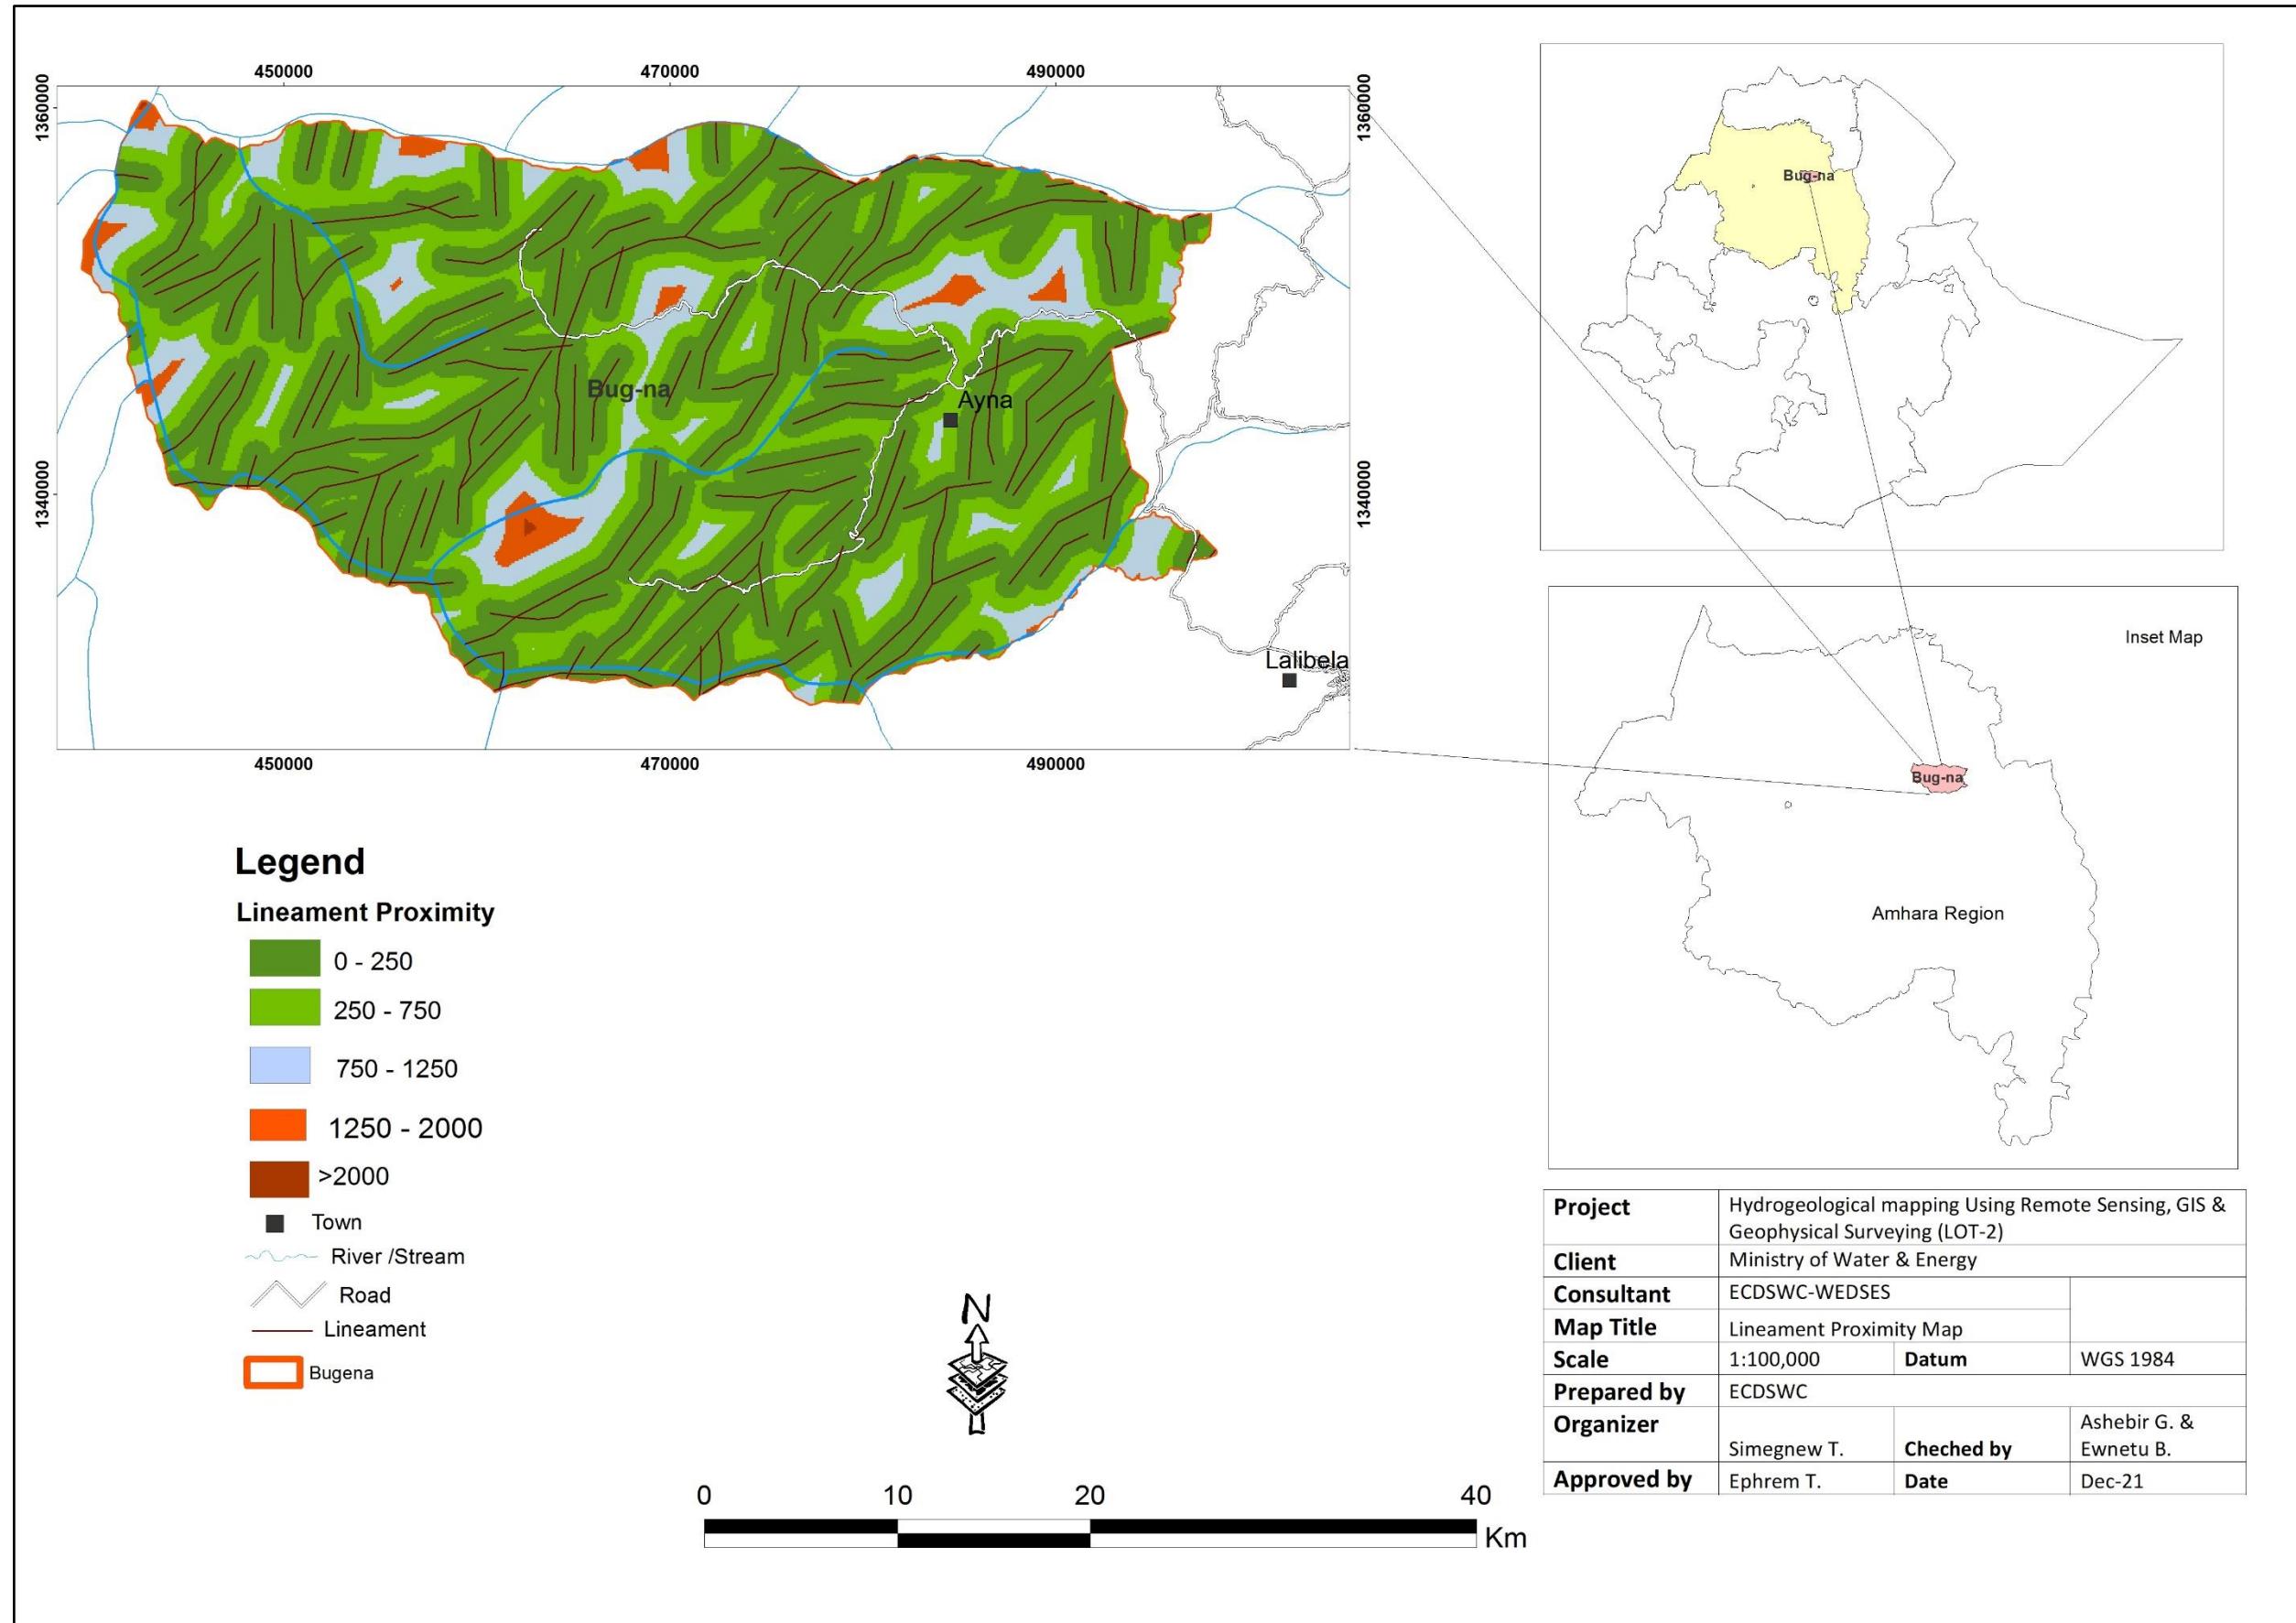

Figure 100: Lineament Proximity Map of Bugna Wereda

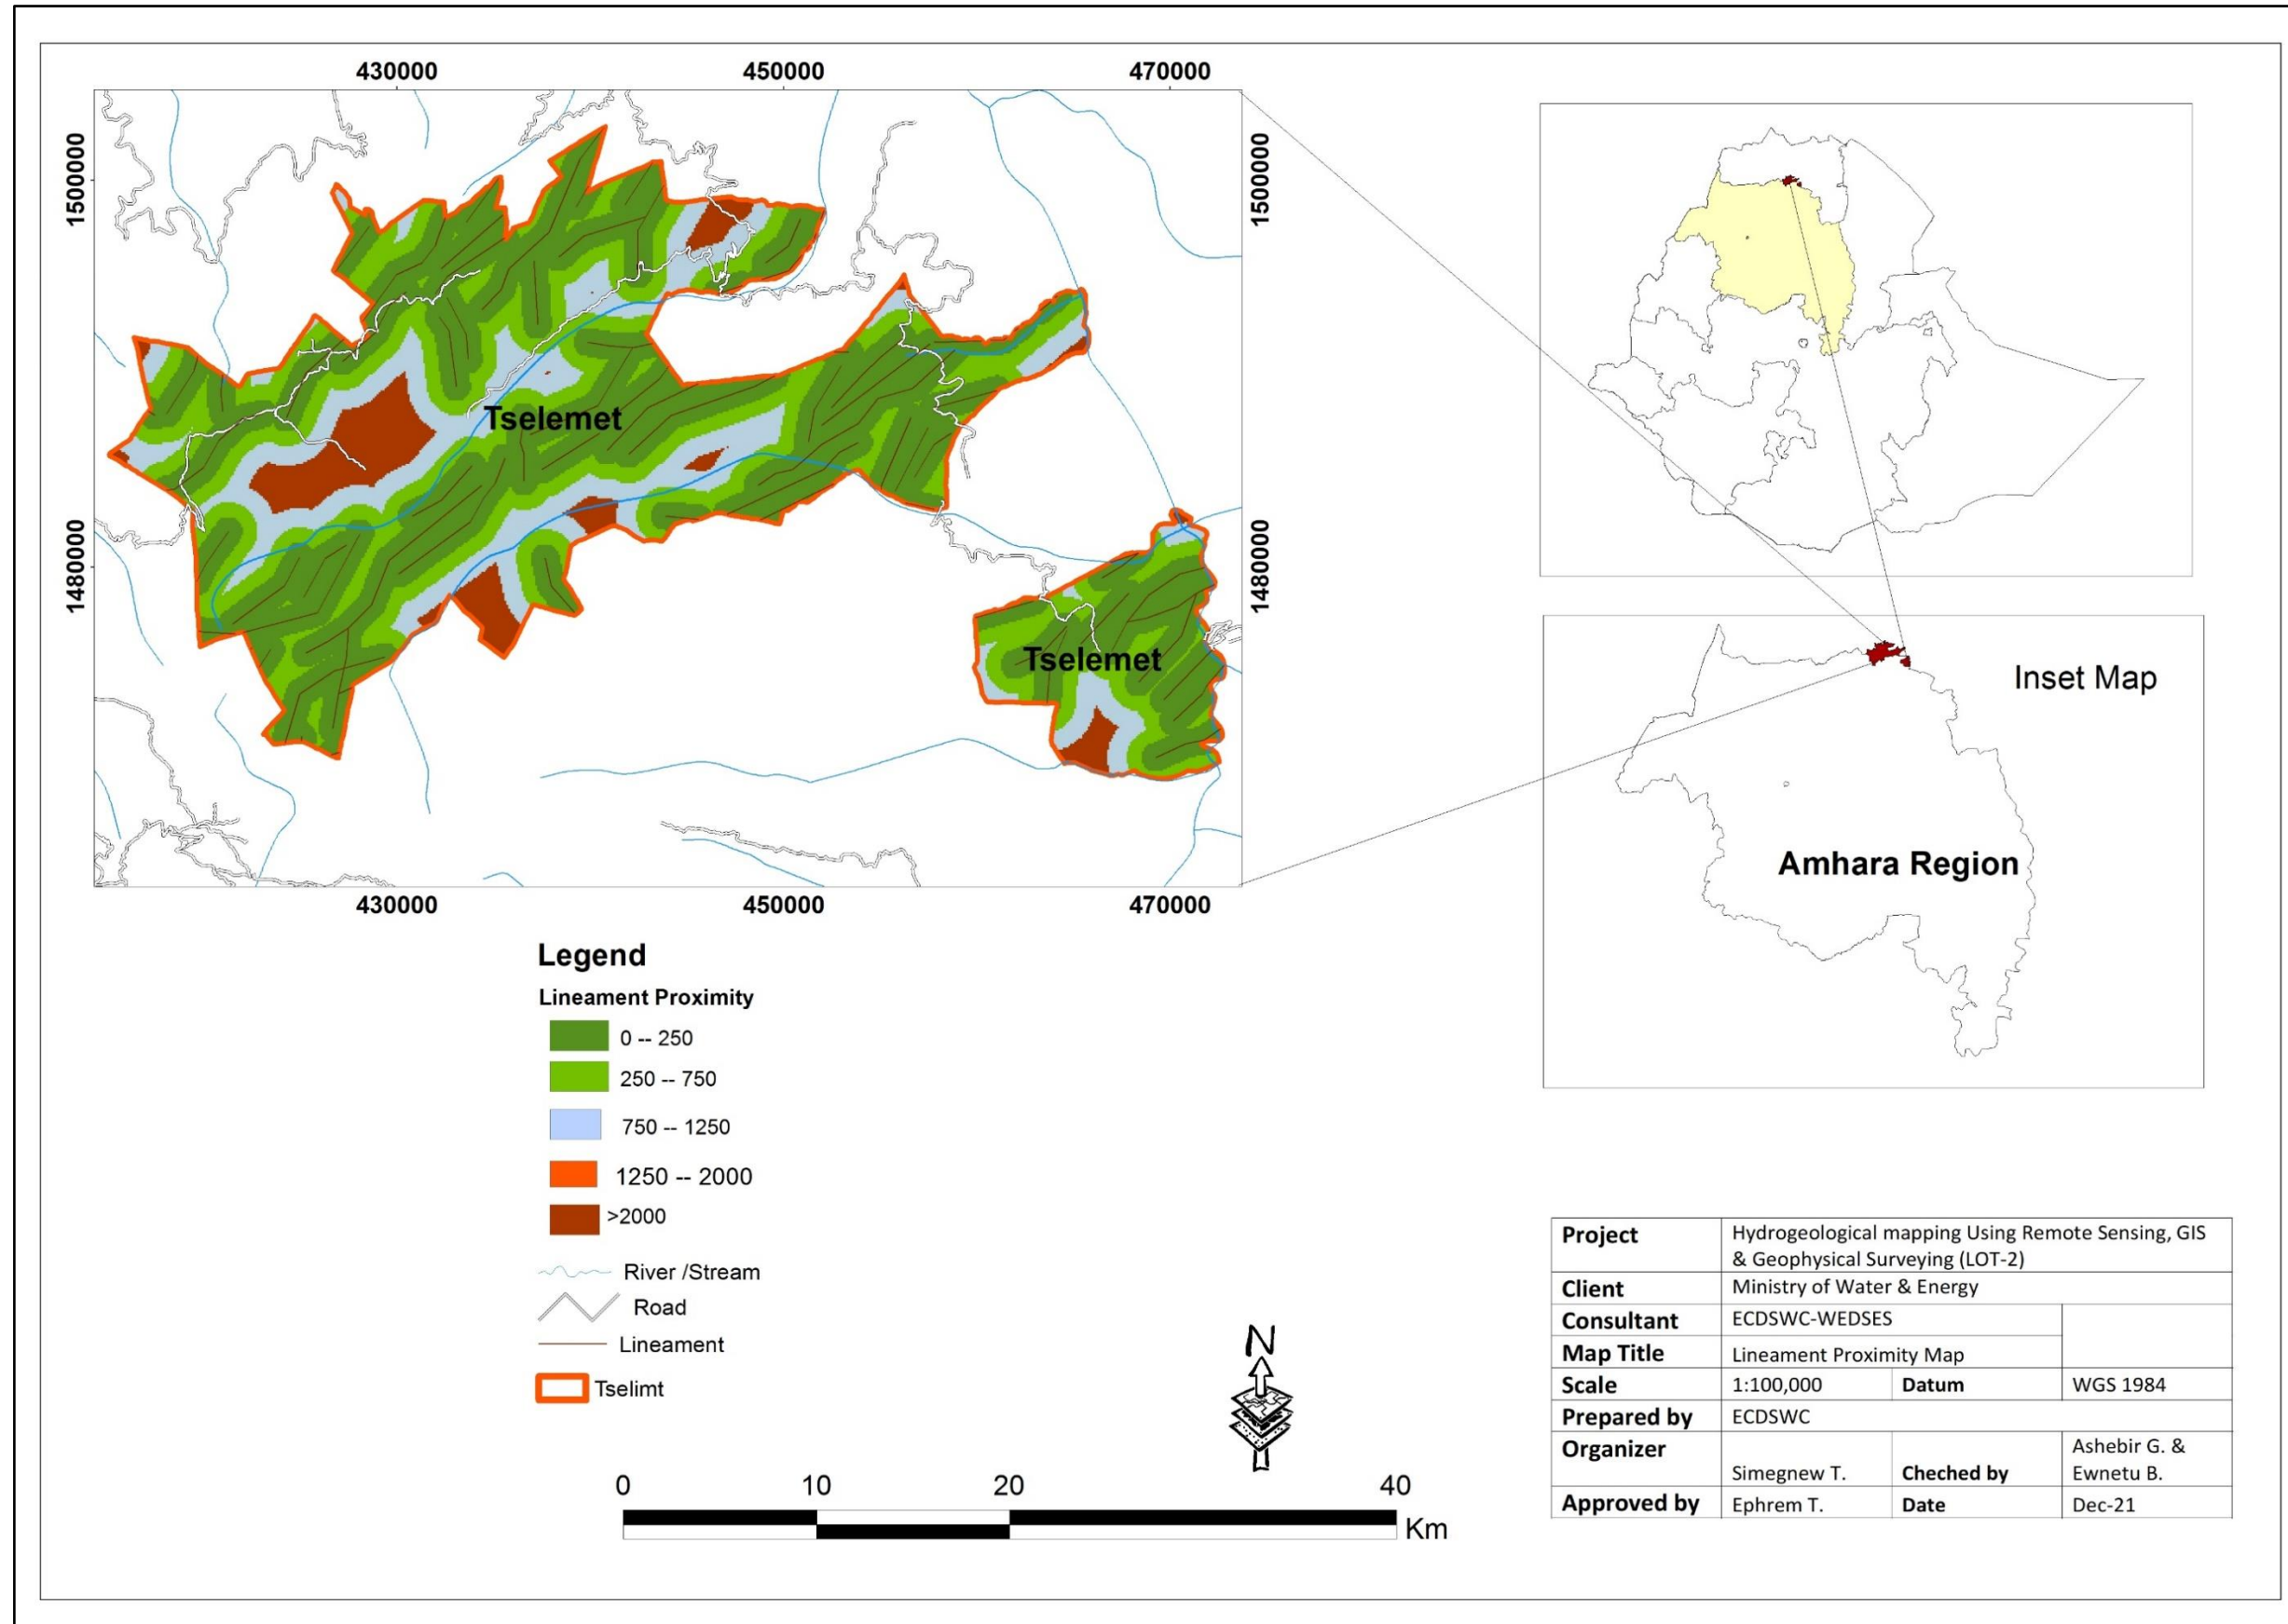

Figure 101: Lineament Proximity Map of Tselemit Wereda

4.3 Overlay analysis

All five thematic layer maps were integrated using ArcGIS 10.8 using the weighted overlay method in the GIS environment to produce the groundwater potential maps of the project weredas. The following formula was used to estimate the groundwater potential maps of the project weredas.

$$GWP = \sum_{i=1}^n wixi \quad \text{-----Eq.7}$$

Where GWP = groundwater potential, Wi = weight for each thematic layer, and Xi = is the ranking of a thematic layer

4.4 Sensitivity analysis

Sensitivity analysis provides important information related to the influence of assigned weights to each thematic layer on the output GWP map. It can indicate which layer is the most / least significant in determining the output map. Hence, single parameter (Napolitano and Fabbri 19996) sensitivity analyses were carried out to justify the influence of thematic layers on the GWP map

The Single – parameter method examines the impact of each thematic layer on the GWP map. This test compares the “effective “or “real” weight for each of the thematic layers with the “Empirical” weight assigned to the same layer in the GWP map. For each thematic layer, the effective weights were calculated using equation (8):

$$W = \frac{PrPw}{GWP} * 100 \quad \text{-----Eq.8}$$

Where W is the effective weight of each thematic layer

Pr and Pw are the rates and weight values of each thematic layer

GWP is the groundwater potential map generated using all the thematic layers.

4.4.1 Single parameter Sensitivity analysis of Argoba Special

The statistics of the single-parameter sensitivity analysis of Argoba Wereda are shown in Table 43. There are some deviations in the effective weights when compared to the empirical weights. The single–parameter analysis of Argoba Wereda shows recharge as the most effective layer in GWP mapping with mean effective weights of 40%. The lineament proximity tends to be a less effective thematic layer with mean effective weightings of 3.3% compared with its empirical weights of 4.36%. The values of mean effective and empirical weight are different for all thematic layers.

Table 43: Effective weight of single parameter sensitivity analyses of Argoba wereda

| The effective weight of Single parameter Sensitivity analysis of Argoba Wereda | | | | | |
|--|----------------------|------|------|------|-------|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 51.63 | 20.8 | 32.2 | 46.3 | 0.195 |
| Recharge | 29.06 | 37.4 | 40.0 | 42.5 | 1.2 |

| TWI | 4.36 | 4.5 | 5.5 | 6.4 | 1.048 |

4.4.2 Single parameter Sensitivity analysis of Bure Mudayitu

The statistics of the single-parameter sensitivity analysis of Buri Mudayitu Wereda are shown in Table 44. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Buri Mudayitu Wereda shows Lithologic units as the most effective layer in GWP mapping with mean effective weights of 63.6%. The lineament density tends to be a less effective thematic layer with the mean effective weight of 4.8% compared with its empirical weights of 8.58%. The values of mean effective and empirical weight are close to each other for Lithologic units, recharge, and TWI layers.

Table 44: Effective weight of single parameter sensitivity analyses of Buri Mudayitu wereda

| The effective weight of Single parameter Sensitivity analysis of Buri Mudayitu Wereda | | | | | |
|---|----------------------|------|------|------|-------|

4.4.3 Single parameter Sensitivity analysis of Dulecha

The statistics of the single-parameter sensitivity analysis of Dulecha Wereda are shown in Table 45. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Dulecha Wereda shows Lithologic units as the most effective layer in GWP mapping with mean effective weights of 41.6%. The TWI and lineament proximity tend to be less effective thematic layers with the mean effective weight of 4.1% and 4.7%. The values of mean effective and empirical weight are close to each other for all layers.

Table 45: Effective weight of single parameter sensitivity analyses of Dulecha wereda

| The effective weight of Single parameter Sensitivity analysis of Dulecha Wereda | | | | | |
|---|----------------------|------|------|------|------|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 35.65 | 29.9 | 41.6 | 53.5 | 1.42 |
| Recharge | 28.52 | 20.6 | 24.7 | 28.8 | 1.36 |
| LD | 26.84 | 19.6 | 24.8 | 29.9 | 1.27 |
| LP | 4.66 | 4.0 | 4.7 | 5.4 | 1.6 |
| TWI | 4.34 | 3.6 | 4.1 | 4.6 | 1.09 |

4.4.4 Single parameter Sensitivity analysis of Wuchale wereda

The statistics of the single-parameter sensitivity analysis of Wuchale Wereda are shown in Table 46. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Wuchale Wereda shows Lithologic units as the most effective layer in GWP mapping with mean effective weights of 56.8%. The TWI and Lineament density tend to be less effective thematic layers with mean effective weightings of 9.3% and 3.4% respectively compared with their empirical weights of 11.9% and 4.6%. The values of mean effective and empirical weight are close to each other for groundwater recharge and Lineament proximity layers.

Table 46: Effective weight of single parameter sensitivity analyses of Wuchale wereda

| The effective weight of Single parameter Sensitivity analysis of Wuchale wereda | | | | | | |
|--|-----------------------------|------------|-------------|------------|-----------|--|
| Effective Weight (%) | | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD | |
| Lithology | 30.7 | 43.6 | 56.8 | 68.7 | 0.9 | |
| Recharge | 25.1 | 19.0 | 25.3 | 31.8 | 2.3 | |
| TWI | 11.9 | 7.9 | 9.3 | 10.8 | 0.4 | |
| LD | 4.6 | 2.8 | 3.4 | 4.0 | 0.9 | |
| LP | 4.5 | 4.2 | 4.7 | 5.3 | 0.3 | |

4.4.5 Single parameter Sensitivity analysis of Girar Jarso Wereda

The statistics of the single-parameter sensitivity analysis of Girar Jarso Wereda are shown in Table 47. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Girar Jarso Wereda shows Lithologic units as the most effective layer in GWP mapping with mean effective weights of 52.9%. The next higher effective weights of 27.4 % were recorded in the groundwater recharge layer. The TWI and Lineament density tend to be less effective thematic layers with mean effective weightings of 10.1% and 3.8% respectively compared with their empirical weights of 11.9% and 4.6%. The values of mean effective and empirical weight are close to each other for the Lineament proximity layers.

Table 47: Effective weight of single parameter sensitivity analyses of Girar Jarso wereda

| The effective weight of Single parameter Sensitivity analysis of Girar Jarso Wereda | | | | | | |
|--|-----------------------------|------------|-------------|------------|-----------|--|
| Effective Weight (%) | | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD | |
| Lithology | 30.7 | 39.7 | 52.9 | 65.5 | 13.2 | |
| Recharge | 25.1 | 20.7 | 27.4 | 34.2 | 4.7 | |
| TWI | 11.9 | 8.5 | 10.1 | 11.7 | 1.5 | |
| LD | 4.6 | 3.1 | 3.8 | 4.4 | 1.0 | |
| LP | 4.5 | 5.2 | 5.9 | 6.6 | 0.5 | |

4.4.6 Single parameter Sensitivity analysis of Kuyu Wereda

The statistics of the single-parameter sensitivity analysis of Kuyu Wereda are shown in Table 48. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Kuyu Wereda shows Lithologic units as the most effective layer in GWP mapping with mean effective weights of 47.2%. The next higher effective weights of 26.7 % and 9.7% were recorded in groundwater recharge and Lineament proximity layers. The TWI and Lineament density tend to be less effective thematic layers with mean effective weightings of 9.3% and 6.6% respectively compared with their empirical weights of 11.7% and 7.6%.

Table 48: Effective weight of single parameter sensitivity analyses of Kuyu wereda

| The effective weight of Single parameter Sensitivity analysis of Kuyu Wereda | | | | | |
|--|----------------------|------|------|------|-----|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 48.3 | 40.2 | 47.2 | 54.4 | 8.5 |
| Recharge | 25.4 | 21.2 | 26.7 | 32.2 | 5.6 |
| TWI | 11.7 | 7.1 | 9.3 | 11.6 | 1.0 |

| LP | 7.1 | 8.5 | 9.7 | 10.9 | 0.5 |

4.4.7 Single parameter Sensitivity analysis of Wuchale Wereda

The statistics of the single-parameter sensitivity analysis of Wuchale Wereda are shown in Table 49. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Wuchale Wereda shows Lithologic units as the most effective layer in GWP mapping with mean effective weights of 48.2%. The next higher effective weights of 25 % and 10.4% were recorded in groundwater recharge and Lineament density layers. The TWI and Lineament proximity tend to be less effective thematic layers with mean effective weightings of 9.6% and 6.3% respectively compared with their empirical weights of 11.7% and 7.1%.

Table 49: Effective weight of single parameter sensitivity analyses of Dera wereda

| The effective weight of Single parameter Sensitivity analysis of Dera wereda | | | | | |
|--|----------------------|------|------|------|------|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 48.3 | 41.1 | 48.2 | 55.2 | 5.95 |
| Recharge | 25.4 | 19.8 | 25.0 | 30.3 | 0.79 |
| TWI | 11.7 | 7.3 | 9.6 | 12.0 | 2.22 |
| LD | 7.6 | 8.5 | 10.4 | 12.4 | 1.75 |
| LP | 7.1 | 5.5 | 6.3 | 7.9 | 0.32 |

4.4.8 Single parameter Sensitivity analysis of Sayit

The statistics of the single-parameter sensitivity analysis of Sayit Wereda are shown in Table 50. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Sayit Wereda shows groundwater recharge as the most effective layer in GWP mapping with mean effective weights of 46.00%. The next higher effective weights of 21.21 % and 13.62% were recorded in Lithologic units and TWI layers respectively. In addition, the Lineament density and Lineament proximity tend to be almost effective thematic layers with mean effective weightings of 9.80% and 9.67% when compared with its empirical weights of 8.4% and 5.8% respectively.

Table 50: Effective weight of single parameter sensitivity analyses of Sayit Wereda

| Thematic Layers | Empirical Weight (%) | Effective Weight (%) | | | |
|---------------------|----------------------|----------------------|-------|-------|------|
| | | Min | Mean | Max | SD |
| Lithology | 42.9 | 18.58 | 21.21 | 23.32 | 2.37 |
| Recharge | 30 | 41.06 | 46.00 | 47.58 | 3.40 |
| TWI | 12.9 | 10.98 | 13.62 | 15.40 | 2.22 |
| Lineament Density | 8.4 | 7.58 | 9.80 | 11.38 | 1.91 |
| Lineament Proximity | 5.8 | 7.83 | 9.67 | 10.89 | 1.54 |

4.4.9 Single parameter Sensitivity analysis of Enebsie Sar Midir

The statistics of the single-parameter sensitivity analysis of Enebise Sar Midir Wereda are shown in Table 51. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Enebise Sar Midir Wereda shows groundwater recharge and Lithologic units as the most effective layer in GWP mapping with mean effective weights of 44.55% and 29.45% respectively. The next higher effective weight of 8.90% was recorded in the Lineament proximity layer. The TWI and Lineament density tend to be less effective thematic layers with mean effective weightings of 11.10% and 6.01% when compared with their empirical weights of 12.9% and 8.4% respectively.

Table 51: Effective weight of single parameter sensitivity analyses of Enebise Sar Midir wereda

| Thematic Layers | Empirical Weight (%) | Effective Weight (%) | | | |
|---------------------|----------------------|----------------------|-------|-------|------|
| | | Min | Mean | Max | SD |
| Lithology | 42.9 | 25.22 | 29.45 | 31.65 | 3.27 |
| Recharge | 30 | 40.75 | 44.55 | 48.36 | 3.81 |
| TWI | 12.9 | 10.51 | 11.10 | 13.66 | 1.67 |
| Lineament Density | 8.4 | 4.67 | 6.01 | 7.08 | 1.21 |
| Lineament Proximity | 5.8 | 7.33 | 8.90 | 10.20 | 1.44 |

4.4.10 Single parameter Sensitivity analysis of Misrak Belesa

The statistics of the single-parameter sensitivity analysis of Misrak Belesa Wereda are shown in Table 52. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Misrak Belesa Wereda shows Lithologic units as the most effective layer in GWP mapping with a mean effective weight of 57.5%. The TWI tend to be less effective thematic layers with mean effective weightings of 2.5% compared with their empirical weights of lineament density, Lineament proximity, and groundwater recharge 13.6%, 13.3, and 13.0% respectively. The values of mean effective and empirical weight are close to each other for TWI and Lineament proximity layers.

Table 52: Effective weight of single parameter sensitivity analyses of Misrak Belesa wereda

| Effective Weight (%) | | | | | |
|----------------------|----------------------|------|------|------|------|
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 41.3 | 53.1 | 57.5 | 61.1 | 2.05 |
| Recharge | 21.5 | 13.8 | 13.0 | 12.2 | 0.14 |
| LD | 21.5 | 14.5 | 13.6 | 12.8 | 0.15 |
| LP | 11.3 | 14.2 | 13.3 | 12.5 | 0.32 |
| TWI | 4.4 | 2.6 | 2.5 | 2.3 | 0.12 |

4.4.11 Single parameter Sensitivity analysis of Ebenat

The statistics of the single-parameter sensitivity analysis of Ebenat Wereda are shown in Table 53. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Ebenat Wereda shows Lithologic units as the most effective layer in GWP mapping with mean effective weights of 44.8%. The next higher effective weights of 19.4 % and 16.7% and 16.1% were recorded in Lineament density, Lineament proximity, and groundwater recharge layers respectively. In addition, the TWI tends to be almost effective thematic layers with mean effective weightings of 2.7% when compared with its empirical weights of 4.4% and.

Table 53: Effective weight of single parameter sensitivity analyses of Ebenat wereda

| The effective weight of Single parameter Sensitivity analysis of Ebenat Wereda | | | | | |
|--|----------------------|------|------|------|-----|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 41.3 | 41.0 | 44.8 | 48.7 | 0.1 |
| Recharge | 21.5 | 17.1 | 16.1 | 15.0 | 0.3 |
| LD | 21.5 | 20.6 | 19.4 | 18.0 | 0.3 |
| LP | 11.3 | 17.9 | 16.7 | 15.6 | 0.2 |

4.4.12 Single parameter Sensitivity analysis of Bugna

The statistics of the single-parameter sensitivity analysis of Bugna Wereda are shown in Table 54. There are some deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Bugna Wereda shows Lithologic units and groundwater recharge as the most effective layer in GWP mapping with mean effective weights of 35.00% and 26.6% respectively. The next higher effective weight of 18.1 and 16.5%% was recorded in Lineament proximity and lineament density layers respectively. In addition, the TWI tends to be almost effective thematic layers with mean effective weightings of 3.7% when compared with its empirical weights of 5.1%.

Table 54: Effective weight of single parameter sensitivity analyses of Bugna wereda

| The effective weight of Single parameter Sensitivity analysis of Bugna Wereda | | | | | |
|--|-----------------------------|------------|-------------|------------|-----------|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 35.5 | 31.0 | 35.0 | 39.5 | 1.8 |
| Recharge | 31.4 | 28.2 | 26.6 | 24.9 | 1.5 |
| LD | 17.3 | 17.6 | 16.5 | 15.3 | 0.2 |
| LP | 10.7 | 19.8 | 18.1 | 16.5 | 0.6 |
| TWI | 5.1 | 4.0 | 3.7 | 3.5 | 0.2 |

4.4.13 Single parameter Sensitivity analysis of Meket

The statistics of the single-parameter sensitivity analysis of Meket Wereda are shown in Table 55. There is some deviation in the effective weights when compared to the empirical weights. The single-parameter analysis of Meket Wereda shows Lithologic units and groundwater recharge as the most effective layer in GWP mapping with mean effective weights of 42.0% and 26.3% respectively. The next higher effective weight of 14.0% and 13.6% was recorded in the Lineament proximity layer and lineament density respectively. In addition, the TWI tends to be almost effective thematic layers with mean effective weightings of 3.5% when compared with its empirical weights of 5.1%.

Table 55: Effective weight of single parameter sensitivity analyses of Meket wereda

| The effective weight of Single parameter Sensitivity analysis of Meket wereda | | | | | |
|--|-----------------------------|------------|-------------|------------|-----------|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 35.5 | 37.7 | 42.0 | 46.6 | 2.6 |
| Recharge | 31.4 | 27.9 | 26.3 | 24.6 | 4.7 |
| LD | 17.3 | 14.4 | 13.6 | 12.7 | 0.4 |
| LP | 10.7 | 15.2 | 14.0 | 12.9 | 0.8 |
| TWI | 5.1 | 3.5 | 3.3 | 3.1 | 0.6 |

4.4.14 Single parameter Sensitivity analysis of Tselemit

The statistics of the single-parameter sensitivity analysis of Tselemit Wereda are shown in Table 56. There are no deviations in the effective weights when compared to the empirical weights. The single-parameter analysis of Tselemit Wereda shows Lithologic units and groundwater recharge as the most effective layer in GWP mapping with mean effective weights of 55.9% and 22.1 % respectively. The next higher effective weight of 15.7% was recorded in the Lineament density layer. The TWI and Lineament proximity tend to be less effective thematic layers with mean effective weightings of 5% and 2.5% respectively.

Table 56: Effective weight of single parameter sensitivity analyses of Tselemit wereda

| The effective weight of Single parameter Sensitivity analysis of Tselemit wereda | | | | | |
|--|----------------------|------|------|------|-----|
| Effective Weight (%) | | | | | |
| | Empirical Weight (%) | Min | Mean | Max | SD |
| Lithology | 41.7 | 46.0 | 55.9 | 68.4 | 5.2 |
| Recharge | 28.9 | 25.0 | 22.1 | 19.1 | 1.8 |
| TWI | 21.8 | 17.8 | 15.7 | 13.5 | 1.8 |

| LP | 3.8 | 2.9 | 2.5 | 2.1 | 0.4 |

4.5 Validation using well data

Introduction

Overlay analysis techniques based on GIS methods have been applied to evaluate the groundwater potential of project weredas. The technique involves setting overlay criteria for the five thematic layers (Lithology, recharge, lineaments density, lineaments proximity, and TWI) by using AHP methods. Layer weights and class have been established based on the developed conceptual model, hydrogeological set up of each wereda, and analysis of previously conducted works. The final output of the work is the production of a groundwater potential map for each wereda classified as very high, high, moderate, low, and very low to demarcate target areas for further detailed hydrogeological and geophysical investigations.

Before proceeding to detail hydrogeological and geophysical investigations, the output of the overlay analysis needs to be validated. In order to validate the overlay analysis results (maps), ground-truthing work has been conducted over each wereda.

To validate the result of overlay analysis, ground-truthing of the work is conducted by comparing it with local and regional hydrogeological and geomorphological conditions and also previously drilled shallow and deep wells. In order to validate produced groundwater potential map, the following steps are followed. Geological and hydrogeological observations

- Regional and local geomorphological settings observation
- Verifications of groundwater potential map with series of ground control
- Water point inventory and comparison of inventoried boreholes characteristics with groundwater potential map
- Checking groundwater potential map produced with general ground conditions

Buri Mudayitu Wereda

Most part of Buri Mudayitu Wereda has been classified as low to very low groundwater potential area except a small portion of moderate groundwater potential delineated in the southwestern part which suits the actual ground conditions.

According to inventoried data of boreholes from this wereda, most of the boreholes drilled on the plain are dry and sunk into clay and lacustrine deposits of low productivity that have a thickness of more than 460 meters. Whereas boreholes (Dengeligita and Gefrem) drilled on the western margin and southern border of the wereda is productive and fractured volcanic rocks are encountered at shallow depth (32m).

Most part of this wereda is swampy and covered by vegetation as observed during our field observation. In addition, lacustrine deposits of different ages covered the plain area and alluvial deposits are exposed on the western margin. From a hydrogeological point of view, hydro lithology of this wereda mapped as the lacustrine deposit is unfavourable for groundwater recharge, flow, and storage even though the topography is suitable. In addition, it fits with produced groundwater potential map (Very low groundwater potential zone).

Alluvial deposits mapped on the western margin and the existence of few lineaments together with its proximity to the western high land and also shallow thickness of alluvial deposit made the western edge of this wereda preferable for groundwater development relatively. However, this area is classified as a low groundwater potential zone on the produced map and requires detailed investigation for groundwater development.

Argoba Liyu Wereda

Most part of Argoba Liyu Wereda is classified as low, moderate, and high groundwater potential area. Topographically, Argoba Liyuwereda is rugged and sloppy and also a number of streams arise from this wereda and flow toward the rift floor. Observed outcrops such as basalt and rhyolite have high and moderate productivity.

Most of Argoba Liyu Wereda areas mapped as low groundwater potential zone are mountainous areas with high slopes. Whereas areas delineated as moderate and high groundwater potential on the produced map are rugged, sloppy, and topographically unsuitable for groundwater development, affected by dense lineament and also dense drainage density.

Deberko borehole (177 meters deep) drilled in the area of dense lineament, drainage density, and relatively low elevation has good yield (5l/s). This point is mapped as a high groundwater potential zone. Whereas areas of high slope within the vicinity of this borehole are mapped as low and moderate groundwater potential.

Dulecha Wereda

Dulecha Wereda is bounded by the Awash River gorge and major marginal faults in the east and west direction. Topographically, Dulecha wereda is plain. However, the plain slightly slopping up to an elevation of more than 1500 meters on the western margin.

According to overlay analysis made to map groundwater potential zones, the western edge of Dulecha wereda and the majority of the area of the central part is mapped as moderate groundwater potential zone. Ignimbrite affected by tectonic forces is observed outcrop on the western edge, whereas the central part is covered by alluvial deposits and less affected by geologic structures. However, validation made by boreholes drilled in the central part shows that boreholes drilled in this area have good yield at shallow depth and this area can be considered as a high to very high groundwater potential zone. The difference observed between potential zone mapped and borehole data deemed arises from high groundwater recharged from subsurface inflow from adjacent aquifers and bank infiltration and seepage of surface rivers.

As depicted on the produced map, areas affected by dense tectonic forces and lithologies of primary and secondary porosities are observed are delineated as high groundwater potential zone.

Wuchale wereda

The groundwater potential map of Wuchale wereda is classified as very low, low, moderate, high, and very high groundwater potential area. Topographical, Wuchale wereda plain land except for the western and southwestern part of the study which is bounded by Muger gorge. The main lithologic unit exposed in the study area is Aiba basalt, Tarmaber basalt, Ashangi basalt, and alluvial formation as very high to low productivity aquifers.

Most of Wuchale wereda areas mapped as moderate to high groundwater potential zones are plain land with moderate groundwater recharge, moderate runoff potential characteristics, and high ability of aquifers (Aiba, Tarmaber basalt, and Alluvial aquifers) to store and convey groundwater through interconnected secondary and primary porosity which is exposed in the major part of the study area. Whereas areas delineated as very low and low groundwater potential is in deep gorge due to unfavourable topographic situation and low storage and transmissivity potential of the exposed Ashangi basalt in the study area.

A total of 10 wells were used for validation, the 9 wells yield values agree with the groundwater potential zone map of Wuchale wereda which fell within moderate to high potential zone. While the other well which fell within the high potential zone map has very high groundwater potential.

Girar Jarso wereda

Girar Jarso wereda aquifer system is classified as very low, low, moderate, high, and very high groundwater potential area. Topographically, the southern part of Girar Jarso wereda is plain land and the northern part is rugged and sloppy topographic setup. The main lithologic unit exposed in the study area is Aiba basalt, Tarmaber basalt, Ashangi basalt, alluvial formation, lower and upper sandstone, and Gohatsion formation mapped as very high to very low productivity aquifers.

The southern part of Girar Jarso wereda is mapped as moderate to high groundwater potential zones because these zones are plain land with moderate groundwater recharge, moderate runoff potential characteristics, and high ability of aquifers (Aiba and Tarmaber basaltic aquifers) to store and convey groundwater through interconnected secondary structures. While the Northern part of Girar Jarso wereda is mapped as a low to very low groundwater potential zone because of the unfavourable topographic setup and the ability of the aquifer to store and transmit groundwater is very low to low potential.

A total of 4 wells and springs were used for validation, the 4wells and 3 spring yield values agree with the groundwater potential zone map of Girar Jarso wereda which fell within low to moderate potential.

Kuyu wereda

Kuyu wereda aquifer system is classified as very low, low, moderate, high, and very high groundwater potential area. Topographical, the Northern part of Kuyu wereda is plain land and the Sothern part is a rugged and sloppy topographic setup. The main lithologic unit exposed in the study area is Aiba basalt, Tarmaber basalt, Ashangi basalt, alluvial formation, lower and upper sandstone, and Gohatsion formation mapped as very high to very low productivity aquifers.

The Northern part of Kuyu wereda is mapped as moderate to very high groundwater potential zones because these zones are plain land with moderate groundwater recharge, moderate

runoff potential characteristics, and high ability of aquifers such as Aiba, Tarmaber, and Alluvial aquifers to store and convey groundwater through interconnected secondary and primary porosity. While the Southern part of Kuyu wereda is mapped as a low to very low groundwater potential zone because of the unfavourable topographic setup and the ability of the aquifer to store and transmit groundwater is very low to low potential natural.

A total of 2 wells and 2 springs were used for validation, the 2 wells and 1 spring yield values agree with the groundwater potential zone map of Kuyu wereda which fell within low to moderate potential. While the other spring which fell within a very high potential zone map has moderate groundwater potential, the unfit observed shall be verified during detailed investigation of Geophysical and Hydrogeological investigation.

Dera wereda

Dera wereda aquifer system is classified as very low, low, moderate, high, and very high groundwater potential area. Topographical, the central and southern central part of Dera wereda is plain land and the areas bound central and southern central land part is rugged and sloppy topographic setup. The main lithologic unit exposed in the study area is Aiba basalt, Tarmaber basalt, Ashangi basalt, lower and upper sandstone, and Gohatsion formation mapped as very high to very low productivity aquifers.

The central and southern central part of Dera wereda is mapped as High to very high groundwater potential zones because these zones are plain land with moderate groundwater recharge, moderate runoff potential characteristics, and high ability of aquifers such as Aiba and Tarmaber basaltic aquifers to store and convey groundwater through interconnected secondary structures. While the areas bound central and Southern central part of Dera wereda is mapped as moderate to very low groundwater potential zone because of the unfavourable topographic setup and the ability of the aquifer to store and transmit groundwater is moderate to very low natural.

A total of 2 shallow wells were used for validation, two wells that fell within the high potential zone map have moderate groundwater potential. The reason may be due to poor construction of wells and or the effect of the gorge surrounding the central and southern central part of Dera wereda.

Enebise Sar Midir Wereda

Most part of Enebise Sar Midir Wereda has been classified as low to very low groundwater potential area except a small portion of moderate groundwater potential zone delineated in the central part and high at the south-eastern and south-western periphery of the wereda which suits the actual ground conditions.

According to the inventoried existing boreholes, 1 well was found in a very low GWP zone ($Q=0.01-0.5l/s$), 8 wells sunk in the low GWP zone ($Q=0.5$ to $2l/s$) with a depth of 55 to 70m and 3 wells at Gunaguna kebele and its surrounding nearby Mertule Maryiam town which are drilled on the north-western part of the wereda sunk in moderate GWP zone of the productive basaltic aquifer ($Q=5.5-10l/s$) with a depth of 153 to 181m.

Most part of this wereda especially in the northern and southern part is rugged with high drainage density and it is not suitable for groundwater exploration only a small portion of an area which is relatively plain land that extends from north-west to the central part which is suitable for groundwater exploration. In which most of the existing boreholes were drilled in this area. There is a scattered vegetation cover and most of the wereda is occupied by

cultivated land as observed during a field visit. In addition, quaternary deposits of alluvial and alluvial sediments are covered the plain area which is exposed on the central part extending to the north-west and south-east direction.

From a hydrogeological point of view, the wereda is represented by rocks of various ages and lithology, starting from the youngest to most recent Quaternary superficial deposits and volcanic rocks, Tertiary basalts, and inter-bedding sediments, to Mesozoic sequences of sandstone, gypsum, and limestone.

Topographically higher plateau areas from the northern part of the area are considered to be the potential recharge areas. This is related to the average annual rainfall received by the highland areas which are characterized by fractured and faulted areas. The lowlands that extend from the north-west to the central part towards the east are considered to be the discharge zones for groundwater.

According to the lithology, the basaltic formation in the northern part gives rise to the existence of dense lineaments together with its proximity to the plain area of this wereda which is the preferable site for groundwater development. However, this area is classified as a moderate to high productive groundwater potential zone on the produced map.

The study area contains the primary structures (sedimentary beds), normal faults, strike-slip faults with associated folds, and lineaments. Lineaments in the area represent joint systems or concealed faults. The joint systems and concealed faults strike NW, NE, and N-S. The joint systems have a vertical dip.

Sayit Wereda

Most part of Sayit Wereda is classified as low and moderate groundwater potential areas, with very rare areas having very low and high groundwater potential. Topographically, this wereda is very rugged, which is part of the central Ethiopian plateau, having small hills and ridges, mountains, escarpments, deep gorges, and sloping topography. The plateau is formed by different flood lava flows of the Tertiary age.

The qualitative investigation includes field observation of the geological, hydrogeological, geomorphological, physical, and geographical setup. Whereas the quantitative investigation is more descriptive and is based on field inventory data, well logging, the yield of springs and wells, and pump test data including permeability, transmissivity, and aquifer thickness. Hence, the lithological units are characterized as porous and fissured permeability as well as impermeable ones. The groundwater flow is mainly through a regularly developed system of fissures of volcanic rocks. The aquifers consist of Upper basalt and pyroclastic rocks of Tarmaber formation.

According to inventoried data of around 33 boreholes from this wereda, which are all shallow in depth not more than 70m drilled on the plain area which sunk into the upper portion of tertiary volcanic of low to moderate productivity in the central and southern part of the wereda, in accordance with the produced map of groundwater potential zone. Out of the inventoried existing boreholes, 12 well were found in very low GWP zone, 13 wells sunk in low GWP zone, and 7 wells which are drilled on the south-western part of the wereda sunk in the low to moderate GWP zone of the productive basaltic aquifer with the depth of 55 to 70m and discharge 0.2 – 8l/s.

Most of Sayit Wereda areas mapped as moderate and high groundwater potential zone are in the plain area. Whereas areas are delineated as low and very low groundwater potential in

the mountainous (rugged) and sloppy areas on the produced groundwater potential zone map and topographically unsuitable for groundwater development, affected by dense lineament and also dense drainage density.

As depicted on the produced map, areas affected by dense tectonic forces and lithologies of primary and secondary porosities are observed are delineated as high groundwater potential zone.

Misrak Belesa Weredas

The groundwater potential map of Misrak Belesa Wereda has been classified as a very low, low, moderate, and high groundwater potential area except for a small portion of very high groundwater potential delineated in the southwestern part which suits the actual ground conditions.

According to inventoried data of boreholes from this wereda, most of the boreholes drilled on volcanic rocks of low productivity that have a thickness of less than 70 meters. Whereas, boreholes (Woiba School and Fisoye) drilled on the western and southern border of the weredas is productive, and fractured volcanic rocks are encountered at shallow depth.

Most parts of these weredas are rugged topography and high gradient coupled with intensive deforestation. This environmental degradation has negatively affected the existence of surface water resources and has resulted in a decline in the productivity of groundwater to the extent that wells and springs have dried up during our field observation. From a hydrogeological point of view, hydro lithology of this wereda mapped as Adigrat sandstone, Lacustrine Sediments, Quaternary alluvium, and unfavourable topography for groundwater recharge, flow and storage even though volcanic rocks looks suitable.

According to overlay analysis made to map groundwater potential zones, the majority area of Misrak Belesa wereda is mapped as a moderate to high groundwater potential zone. However, validation made by boreholes drilled in the central part shows that boreholes drilled in this wereda area have low to very high yield at shallow depth and these areas can be considered as moderate to high groundwater potential zone. Except for a few wells, the groundwater potential map agrees with the yield wells. The difference observed between potential zone map and few borehole data deemed arises from poor well construction and or the effect of structure in which align SW – NE direction toward deep Tekeze gorge.

Ebenat Weredas

The groundwater potential map of Ebenat Wereda has been classified as a very low, low, moderate, and high groundwater potential area.

According to inventoried data of boreholes from this wereda, most of the boreholes drilled on volcanic rocks of low productive that have a thickness less than 70 meters. Whereas boreholes (Wegerie, Tuchamesk, Nill) drilled on the southern and western border of the wereda is productive, fractured volcanic rocks are encountered at shallow depth.

Most part of this wereda is rugged topography and high gradient coupled with intensive deforestation. This environmental degradation has negatively affected the existence of surface water resources and has resulted in a decline in the productivity of groundwater to the extent that wells and springs have dried up during our field observation. From a hydrogeological point of view, hydro lithology of this wereda mapped as Lacustrine Sediments, Quaternary alluvium,

and unfavourable topography for groundwater recharge, flow and storage even though volcanic rocks look suitable.

According to overlay analysis made to map groundwater potential zones, the majority area of the most southern part of Ebenat wereda is mapped as low groundwater productive while most central Easter and northern parts of Ebenat wereda are mapped as moderate to high groundwater potential zone. However, validation made by boreholes drilled in most central and northern parts shows that boreholes drilled in this wereda have low to moderate yield at shallow depth and the south-western part of this area is moderate to high yield. Except for few wells the groundwater potential map agrees with the yield wells. The difference observed between potential zone map and few borehole data deemed arises from poor well construction and or the effect of structure in which align SW – NE direction toward deep Tekeze gorge.

Bugna Wereda

Bugna Wereda GWP map is classified as a very low, low, and moderate groundwater potential area. Topographically this wereda is rugged and sloppy and a number of streams arise from this wereda and flow toward the Tekeze. Observed outcrops such as basalt and trachyte have low to high productivity.

Most of these wereda areas mapped as low groundwater potential zone are mountainous areas with high slopes. Whereas areas delineated as moderate and high groundwater potential produced on the map are rugged, sloppy, and topographically unsuitable for groundwater development, affected by dense lineament and also dense drainage density.

Ayinan Eyesus (43-meter depth) drilled in an area of dense lineament, drainage density, and relatively low elevation has a high yield (7 l/s). This point is mapped as a moderate groundwater potential zone. Whereas areas of high slope within the vicinity of this borehole are mapped as low and moderate groundwater potential.

Meket Wereda

Mekiet Wereda is bounded by the water divide and major marginal faults in the east and west direction. Topographically, Mekiet wereda represents the high flatlands around Debre Zebith. It also includes other slightly denuded landscapes. This region is the result of erosion and degradation of remnants of volcanic rocks.

According to overlay analysis made to map groundwater potential zones, the western and most eastern edges of this wereda is mapped as low to moderate groundwater potential zone. Pyroclastic and trachytes are observed outcrop on the east western edge, whereas the central and most northern and the tip of the southern part is covered by basalt and less affected by geologic structures. Validation made by boreholes drilled in the east-west margin part shows that boreholes drilled in this area have low to high yield and this area can be considered as a moderate groundwater potential zone based on potential zone map and validation points.

Tselemit Wereda

The hydrogeological setup of the area shows the major sources of recharge for the study area (Tselemit Wereda) is assumed to be from Ras-Dashen Mountain composed of mainly tertiary trap volcanics to the northeastern direction toward Tekeze gorge through fractured, dissected intermountain valleys of erosional effects and jointed tertiary basalts.

In addition, geomorphological setup, geologic structures, NE river orientations in the Tselemit wereda shows that the groundwater recharged on the highland areas of Ras-Dashen Mountain is anticipated to get the highest annual rainfall and flows toward the Tekeze river gorge. According to the preliminary hydrogeological map of the area depicted below the study, wereda is found mainly within the extensive and moderately productive fissured aquifers of the tertiary trap basalts.

According to overlay analysis made to map groundwater potential zones, the northeastern and most central part of this wereda is mapped as moderate to very high groundwater potential zone. Validation made by boreholes drilled in the central and northeast part shows that boreholes drilled in this area have very high to moderate yield at shallow depth and these areas can be considered as high groundwater potential zone based on potential zone map and validation points.

As shown on produced map, areas affected by dense tectonic forces and lithologies of primary and secondary porosities are observed are delineated as moderate groundwater potential zone. A total of 3 wells were used for validation, the 2 wells yield values agree with the groundwater potential zone map of Tselemit wereda which fell within moderate to high potential. While the other well which fell within a low potential zone map has moderate groundwater potential, the unfit observed may be due to poor well construction and this study shall be verified during detailed investigation of Geophysical and Hydrogeological investigation. In addition, it is recommended that this study shall be supported by test well drilling.

4. 6. Socio - Economy and water demand of Project weredas

To estimate the water demand of the project weredas CSA projected population data of July 2021 is used. As per the GTP-2 (2016-2020) water supply service level standard, it is required to provide safe water in a minimum of 25 l/c/day within a distance of 1 km for rural areas while in urban areas it is required to provide safe water in a minimum of 100 l/c/day for category 1 towns/cities (towns/cities with a population more than 1 million), 80 l/c/day for category 2 towns/cities (towns/cities with a population in the range of 100,000-1million), 60 l/c/day for category 3 towns/cities (towns/cities with a population in the range of 50,000 -100,000), 50 l/c/day for category 4 towns/cities (towns/cities with a population in the range of 20,000-50,000) up to the premises, and 40 l/c/day for category-5 towns/cities (towns/cities with a population less than 20,000) within a distance of 250m.

The water demand of the project weredas for water supply of small-town, livestock & rural water supplies water demand are summarized in the table below.

4.6.1 water demand of cluster 1

5. Revised work plan for the phase – III

The Revised Work Programs for Phase III is prepared considering the remaining work volume. Accordingly, the revised work program is prepared for phase III and is given in Figure 130.

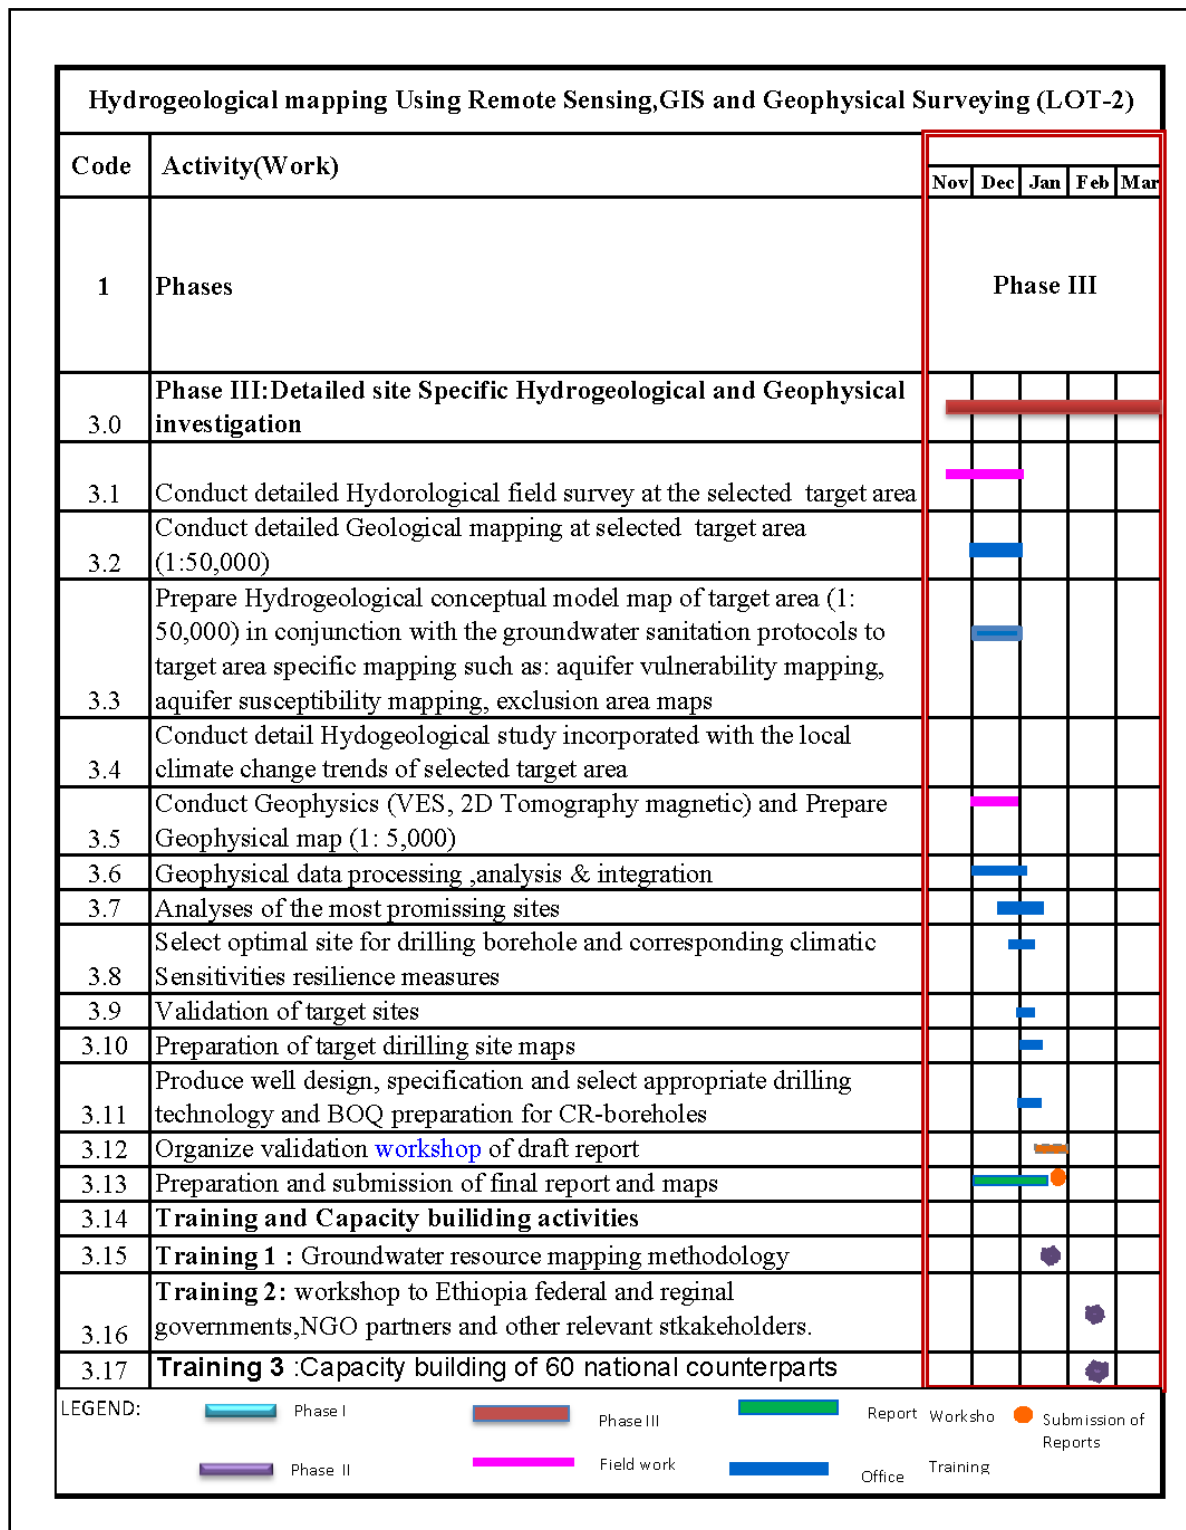

Figure 130: Revised Work Program for phase III work activities

6. Conclusion and Recommendation

The present study is an attempt to delineate the groundwater potential zones using RS, GIS, and MCDM techniques in 14 weredas, which are located in Afar, Amhara, and Oromia regional states. A total of five thematic layers such as Lithologic units, Lineament density, Lineament proximity, TWI, and Recharge were used in this study to delineate the groundwater potential zones. Different steps chosen for the study include the development of the thematic layers followed by GIS-based Multi-Criteria evaluation based on saaty's analytical hierarchy process (AHP) is used to compute weights for the thematic layers, the ranks from 1 to 5 allocated for each thematic layer which indicates very low, low, medium, high and very high in ascending order, associated with each class, were selected based on the influence of each factor on the groundwater potential, weighted overlay analyses for the demarcation of GWP zones, sensitivity analyses to understand effect weight of each thematic layer and validation of GWP zone by using well data and conceptual understanding of each project weredas.

The spatial distribution of the project weredas GWP zones generally matches with the conceptual understanding of the project weredas and well data during model validation. The good agreement of GWP map validation and well data indicate litho–structural control on groundwater recharge and movement process and factors affecting groundwater recharge were carefully analyzed during the development of thematic layers. Based on the result of sensitivity analysis, the effective weights for each thematic layer show some deviation from empirical weights. The GWP maps produced will be used to quickly identify the prospective GWP zones for conducting site-specific investigations.

This study generally demonstrates that GIS and remote sensing techniques coupled with field data can be used for mapping GWP zones, thereby narrowing down the target areas. Then, by conducting a detailed hydrogeological and geophysical survey at phase III, the most appropriate and optional sites will be selected for drilling.

It recommended that this study must be supported by detailed Hydrogeological, Geophysical, and test well drilling to more understand the groundwater system of the project areas.

Annex 1: Observation during groundwater truthing and validation

Cluster 1

| No. | Wereda | Locality | UTM E | UTM N | Elv. | Characteristic of validation point |
|-----|----------------------|-----------------|--------|---------|------|---|
| 1 | Buri Mudayitu wereda | Dengeligita | 649387 | 1115566 | 638 | <ul style="list-style-type: none"> The observation point is mountain side, there is one deep well with unknown discharge but currently functional, no shallow well, no hand dug well, no spring and alluvial deposit is the observed formation The area is mapped as low groundwater potential zone |
| 2 | | Buri | 666420 | 1138650 | 562 | <ul style="list-style-type: none"> The observation point is on flat plain sloping up to NE areas. There is one deep (400 meter) and dry well, no shallow well, no hand dug well & no spring. Lacustrine deposit and clay is observed formations of the area. The area is mapped as very low groundwater potential zone |
| 3 | | Gefrem | 663399 | 1102584 | | <ul style="list-style-type: none"> The observation point is close to Awash river. There is one borehole of unknown depth and 3.5 l/s yield. Lacustrine deposit is observed formations of the area. The area is mapped as very low groundwater potential zone. However, promising yield (3.5) and shallow static water level (3m) of inventoried borehole shows that bank infiltration of nearby Awash River deemed to recharge the groundwater. |
| 4 | Argoba Liyu Wereda | Deberko | 594802 | 1068439 | 1561 | <ul style="list-style-type: none"> The observation point is rugged, sloppy and there are dense drainage and lineament density. Borehole of 177 meter depth & yields 5 l/s exists in the area. The area is mapped as high groundwater potential zone |
| 5 | | Gacheni | 597044 | 1057270 | 716 | <ul style="list-style-type: none"> The observation point is close Gacheni town at junction of two rivers, there is one well with unknown depth but currently functional, no shallow well, no hand dug well, no spring and basalt and rhyolite covered by top soil is the observed formations. The area is mapped as moderate groundwater potential zone |
| 6 | | Metekleya | 596124 | 1045870 | 1187 | <ul style="list-style-type: none"> The observation point is mountainous, sloppy and located in river valley. Borehole of 150 meter depth exists in the area. The vicinity of observation point is close to head water of the area. The area is mapped as low groundwater potential zone |
| 7 | Dulecha | Dulecha Town | 604874 | 1055711 | 1026 | <ul style="list-style-type: none"> The observation point is close to Dulecha town. Tophographically the area is gently sloping and rivers that flows in almost W-E direction exists. Alluvial deposit is observed exposure and there are numerous NE-SW trending marginal faults and lineaments with in the vicinity. One borehole (unknown depth & discharge) currently serving Dulecha town is located at this observation point. From hydrogeological point of view, the observed point has good water potential due to hydrogeological set up of the area. The area is mapped as High groundwater potential zone |
| 8 | | Lalaba/ Hurunto | 621058 | 1047070 | 749 | <ul style="list-style-type: none"> Alluvial deposit is exposure that covers this observation point. The area is gently sloping, a number of streams arises from western margin flows through the area towards Awash river. NE-SW major faults are observed within the vicinity and one borehole (100 m deep) drilled on the edge of this fault yields 24l/s. In terms of groundwater potential the observation point is deemed to be good due to existence good productive lithologies that exhibit primary and secondary porosities, high groundwater recharge from subsurface inflow from adjacent aquifers, river bank infiltration and direct rainfall. The area is mapped as moderate groundwater potential zone due to the fact that only recharge from direct rainfall is considered for the overlay analysis recharge estimation. |
| 9 | | Western area | 600668 | 105492 | | <ul style="list-style-type: none"> The observation point is mountainous, sloppy and located in river valley. No deep & shallow well, no hand dug well, no spring and Ignimbrite affected by tectonic force is the observed outcrop. The area is mapped as Moderate groundwater potential zone |

Cluster 2

| No. | Wereda | Locality | UTM E | UTM N | Characteristic of validation point |
|-----|--------------------|-----------------|--------|---------|---|
| 1 | Wuchale Wereda | Tulu Gerbicho | 509685 | 1078701 | <ul style="list-style-type: none"> The observation point is plain land with moderate groundwater recharge and Runoff potential. One well is observed with discharge of 8l/s. Alluvial aquifer with moderate to high groundwater potential is observed lithological unit in this area. The area is mapped as high groundwater potential zone. The groundwater potential map show there is good agreement between the well discharge and groundwater potential map. |
| 2 | | Burka Dandi | 495822 | 1064653 | <ul style="list-style-type: none"> The observation point is plain land with moderate groundwater recharge and Runoff potential. One well is observed with discharge of 13 l/s. Aiba basalt is lithological unit observed in this area. The area is mapped as high groundwater potential zone which highly agree with the well discharge observed in this zone. |
| 3 | | Halko | 473683 | 1062937 | <ul style="list-style-type: none"> The observation point is plain land with moderate groundwater recharge and Runoff potential. Two well is observed with discharge of 5 & 7 l/s. Alluvial aquifer is lithological unit observed in this area. The area is mapped as moderate to high groundwater potential zone which highly agree with the well discharge observed in this zone. |
| 4 | | Sadan | 487195 | 1056852 | <ul style="list-style-type: none"> The observation point is plain land with moderate groundwater recharge and Runoff potential. One well is observed with discharge of 3.06 l/s. Aiba basalt is lithological unit observed in this area. The area is mapped as moderate groundwater potential zone which highly agree with the well discharge observed in this zone. |
| 5 | Girar Jarso Wereda | Wisi Biriqe | 475032 | 1087994 | <ul style="list-style-type: none"> The observation point is plain land and Tarmaber basalt is the lithological unit mapped in this area. Spring discharge of 3.5 & 3 l/s exists in the area. The area is mapped as moderate to high groundwater potential zone |
| 6 | | Changel | 480142 | 1074817 | <ul style="list-style-type: none"> The observation point is plain land with low to moderate groundwater potential and recharge potential. One borehole taped in basaltic aquifer with yield 3.3 l/s. The area is mapped as moderate groundwater potential The area is mapped as moderate groundwater potential zone which highly agree with the well discharge observed in this zone. |
| 7 | | Mesk woha | 475032 | 1087994 | <ul style="list-style-type: none"> The observation point is mountainous, sloppy and located at contact of Ashangi basalt and Gypsum. The observation point is low groundwater potential and recharge potential. One spring with discharge of 1.6 l/s exist in the area. The area is mapped as low groundwater potential zone which highly agree with the spring discharge observed in this zone |
| 8 | Kuyu Wereda | Derach cagi | 414526 | 1083262 | <ul style="list-style-type: none"> The observation point is plain land with moderate recharge and runoff potential. Alluvial aquifer with moderate permeability is observed lithological unit in this area. The observation point is mapped as high groundwater potential zone .However one borehole drilled in this area with moderate groundwater discharge about 4l/s. This miss match may be observed may be due to poor construction of borehole, pumping test and Limited lineament density in this area. Generally, further geophysical investigation and detail hydrogeological mapping will verify the groundwater potential map of this area. |
| 9 | | Dawicha Kerensa | 434702 | 1076942 | <ul style="list-style-type: none"> The observation point is mountainous and sloppy land. One spring is observed with discharge of 4 l/s at contact of Aiba basalt and Antalo Limestone. The area is mapped as high to very high groundwater potential zone. Generally, further test well drilling , detail hydrogeological and geophysical investigation will be required to verify the aquifer potential of this area. |
| 10 | | Jila Keransa | 432189 | 1071983 | <ul style="list-style-type: none"> The observation point is mountainous and sloppy land. The area is characterized as high runoff potential and low recharge potential. One spring is observed with discharge of 2 l/s at contact of Antalo Limestone and gypsum. |

Annex 3: Geologic map and cross section of Project Weredas

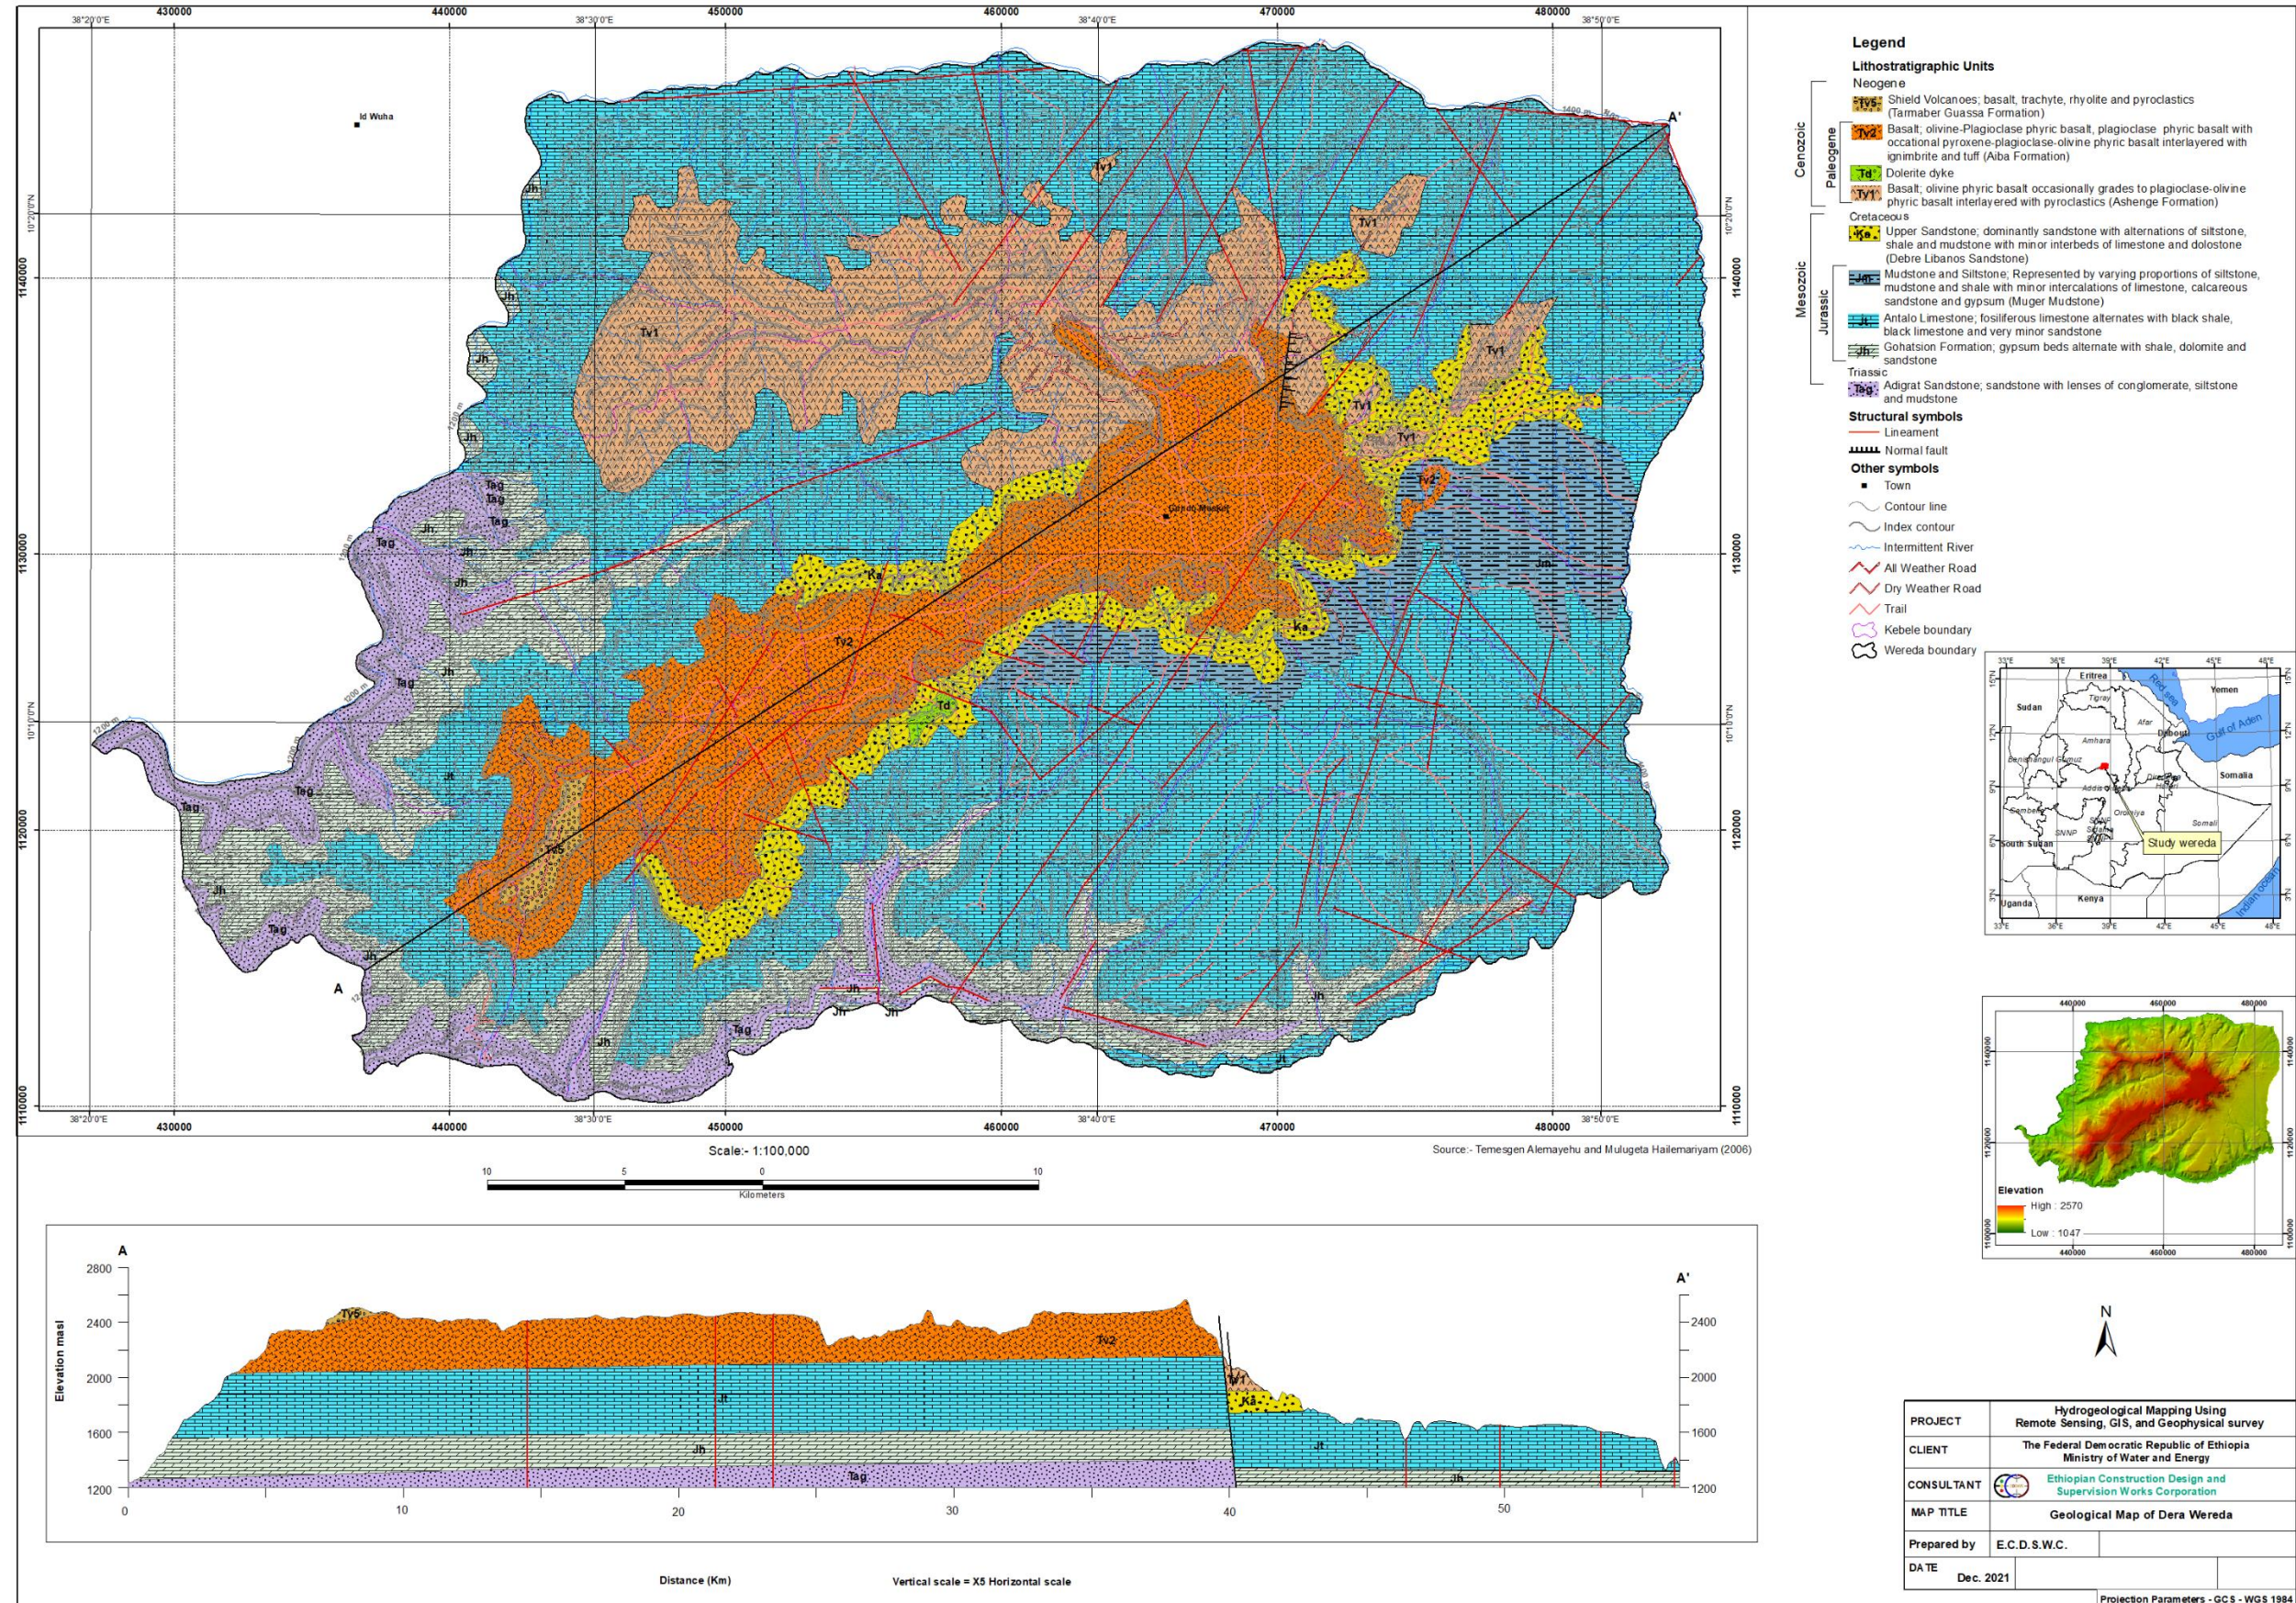

Geological map and cross section of Dulecha Wereda

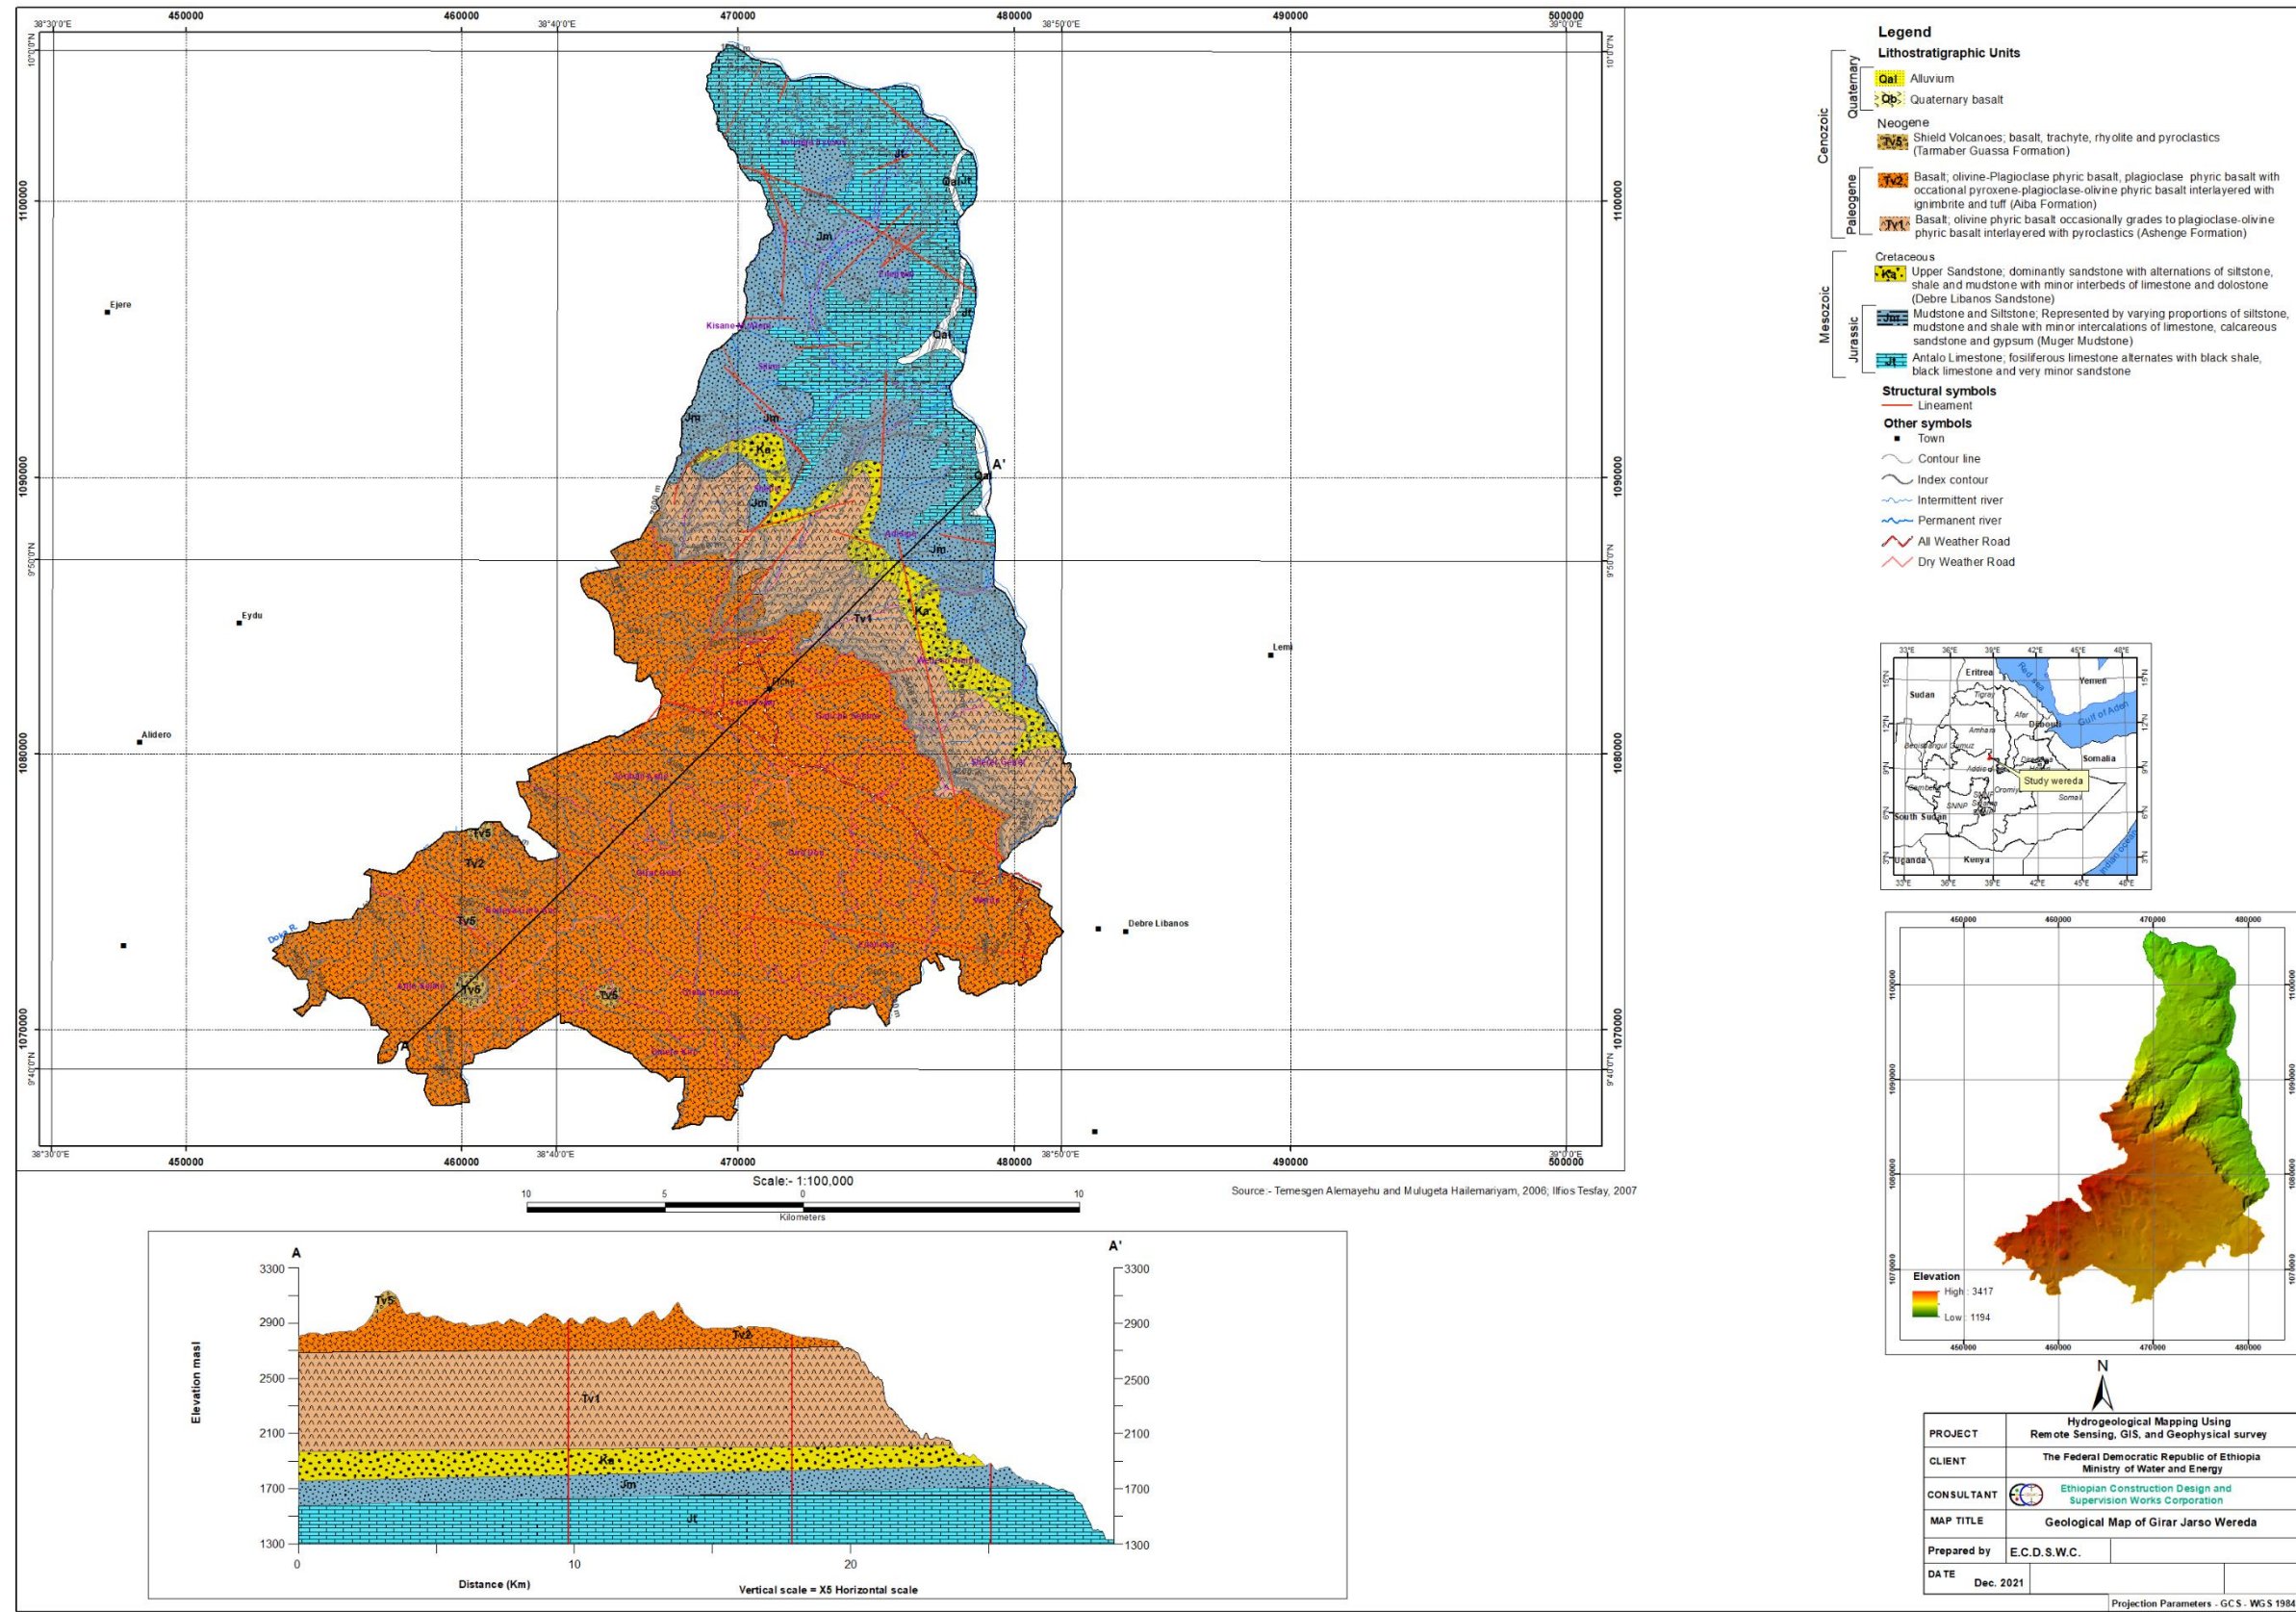

Geological map and cross section of Argoba Liyu Wereda

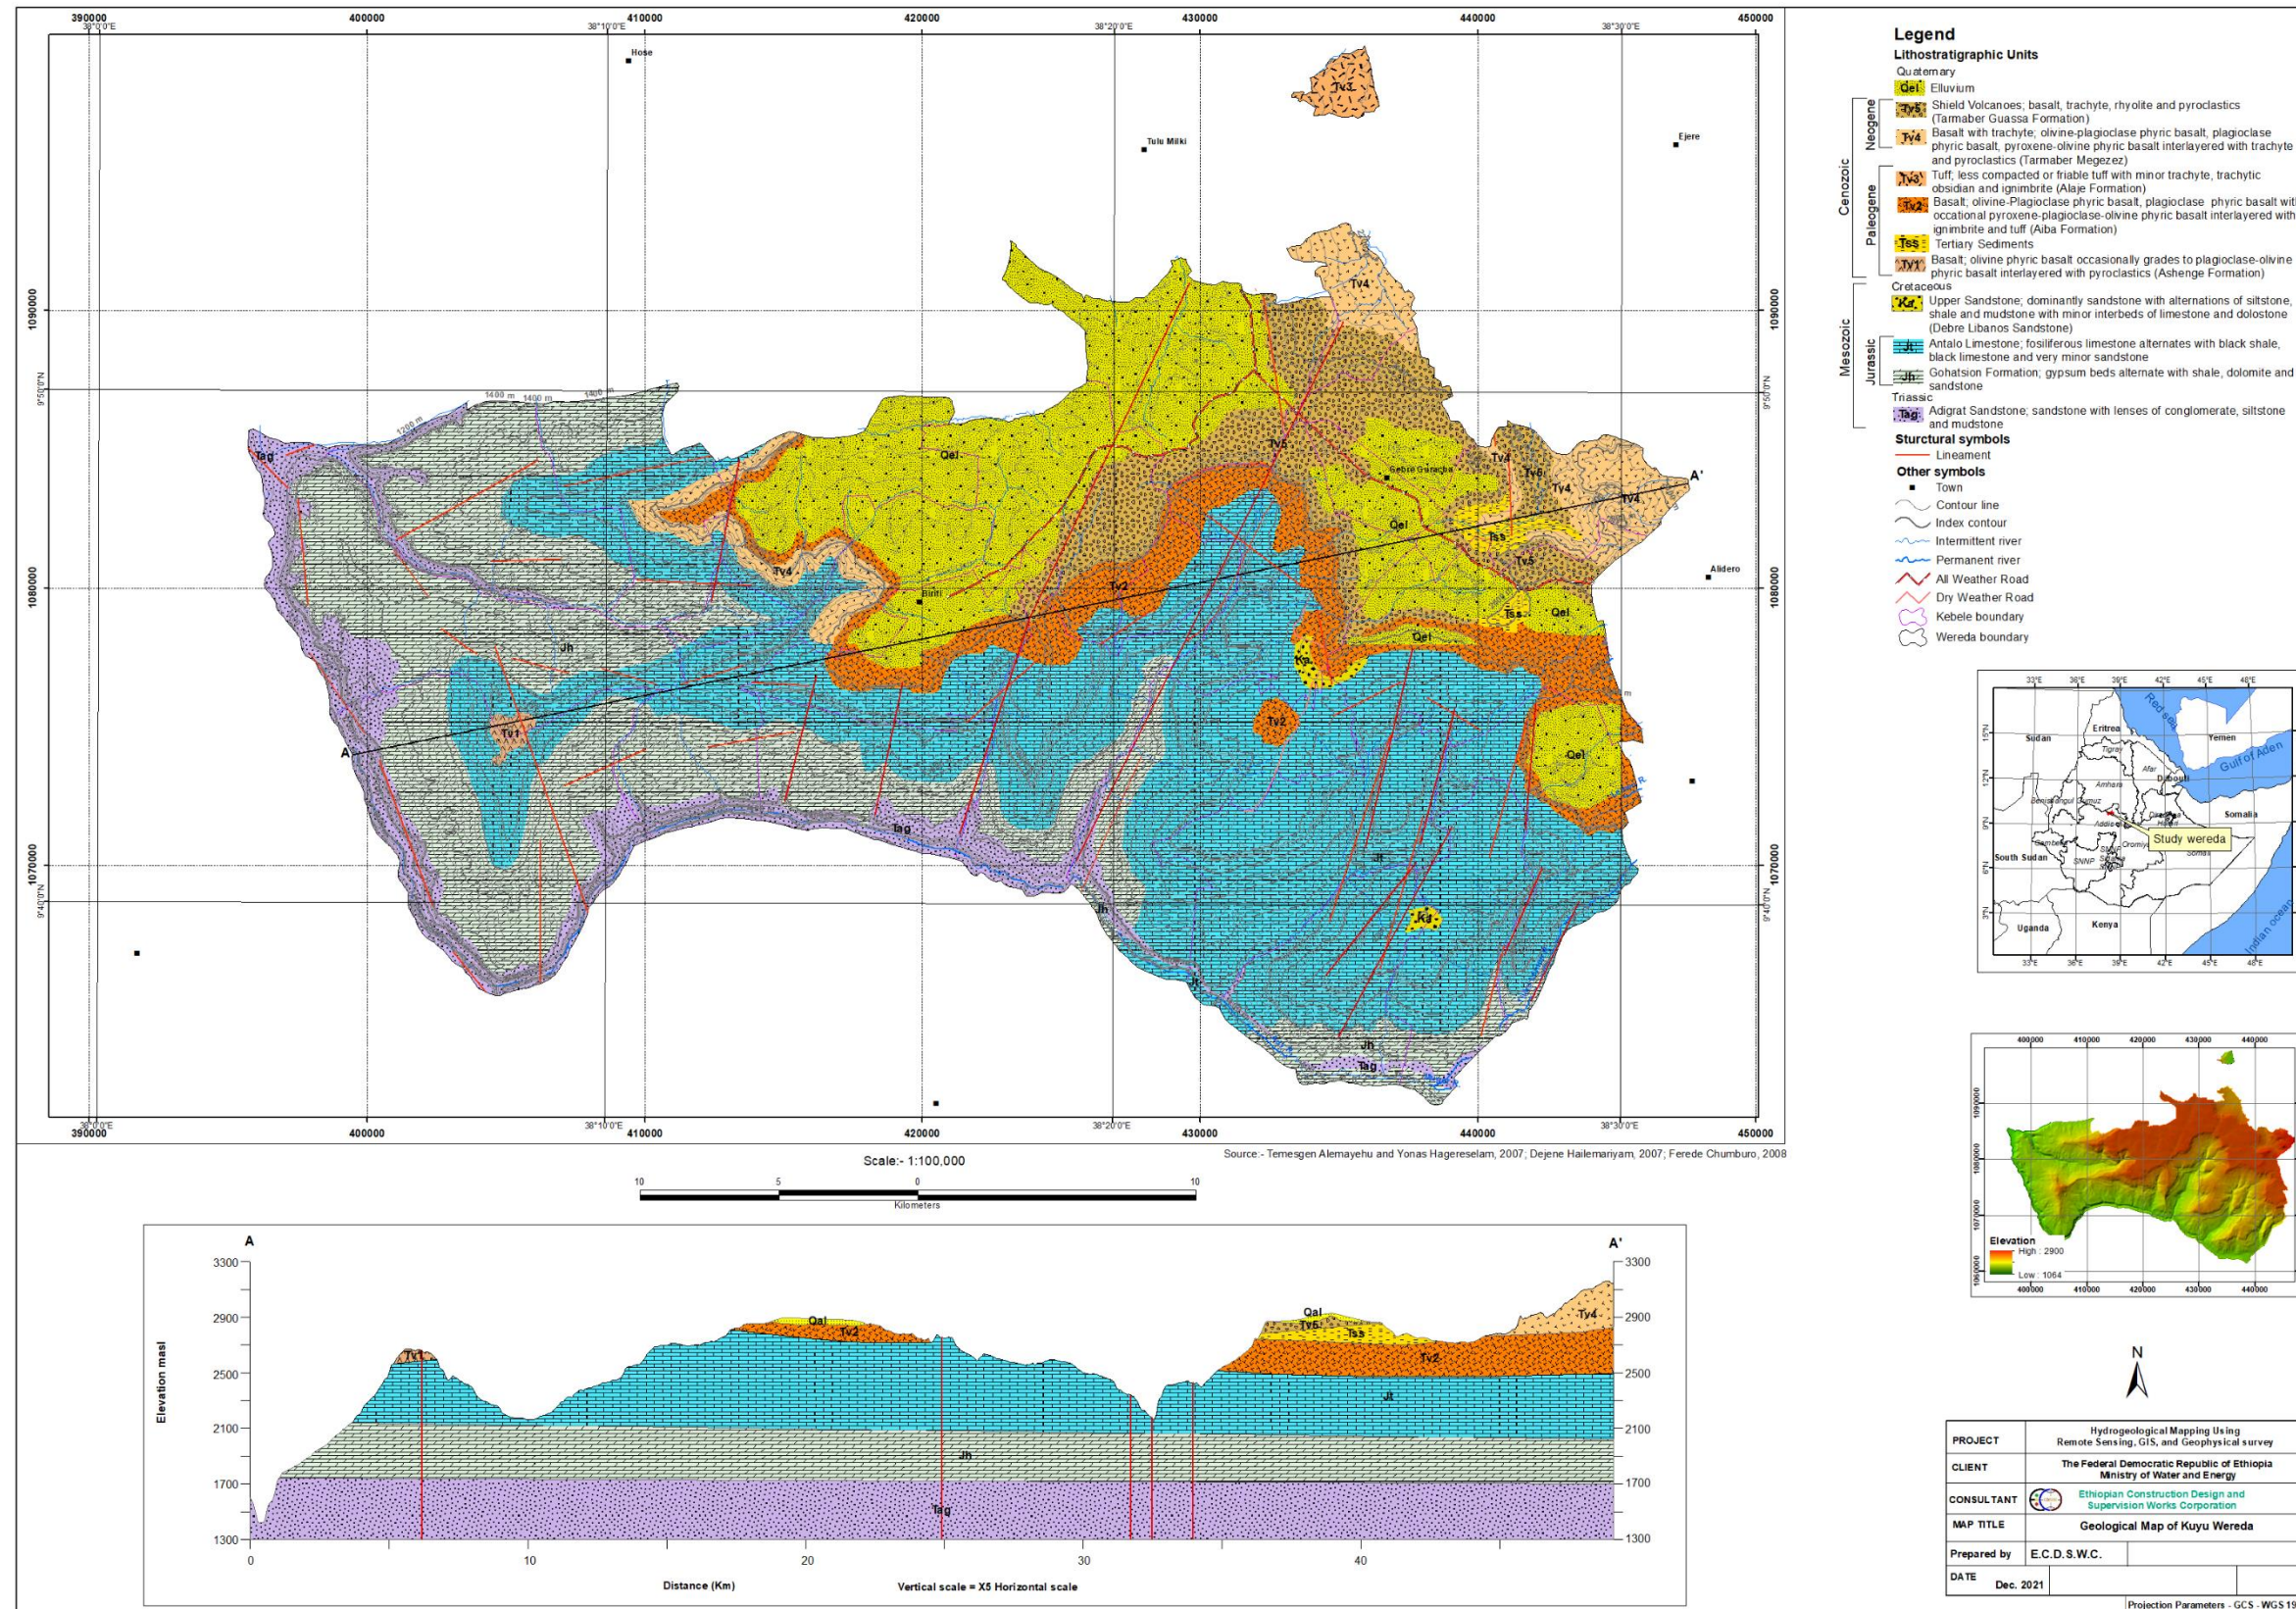

Geological map of Bure Mudayitu Wereda

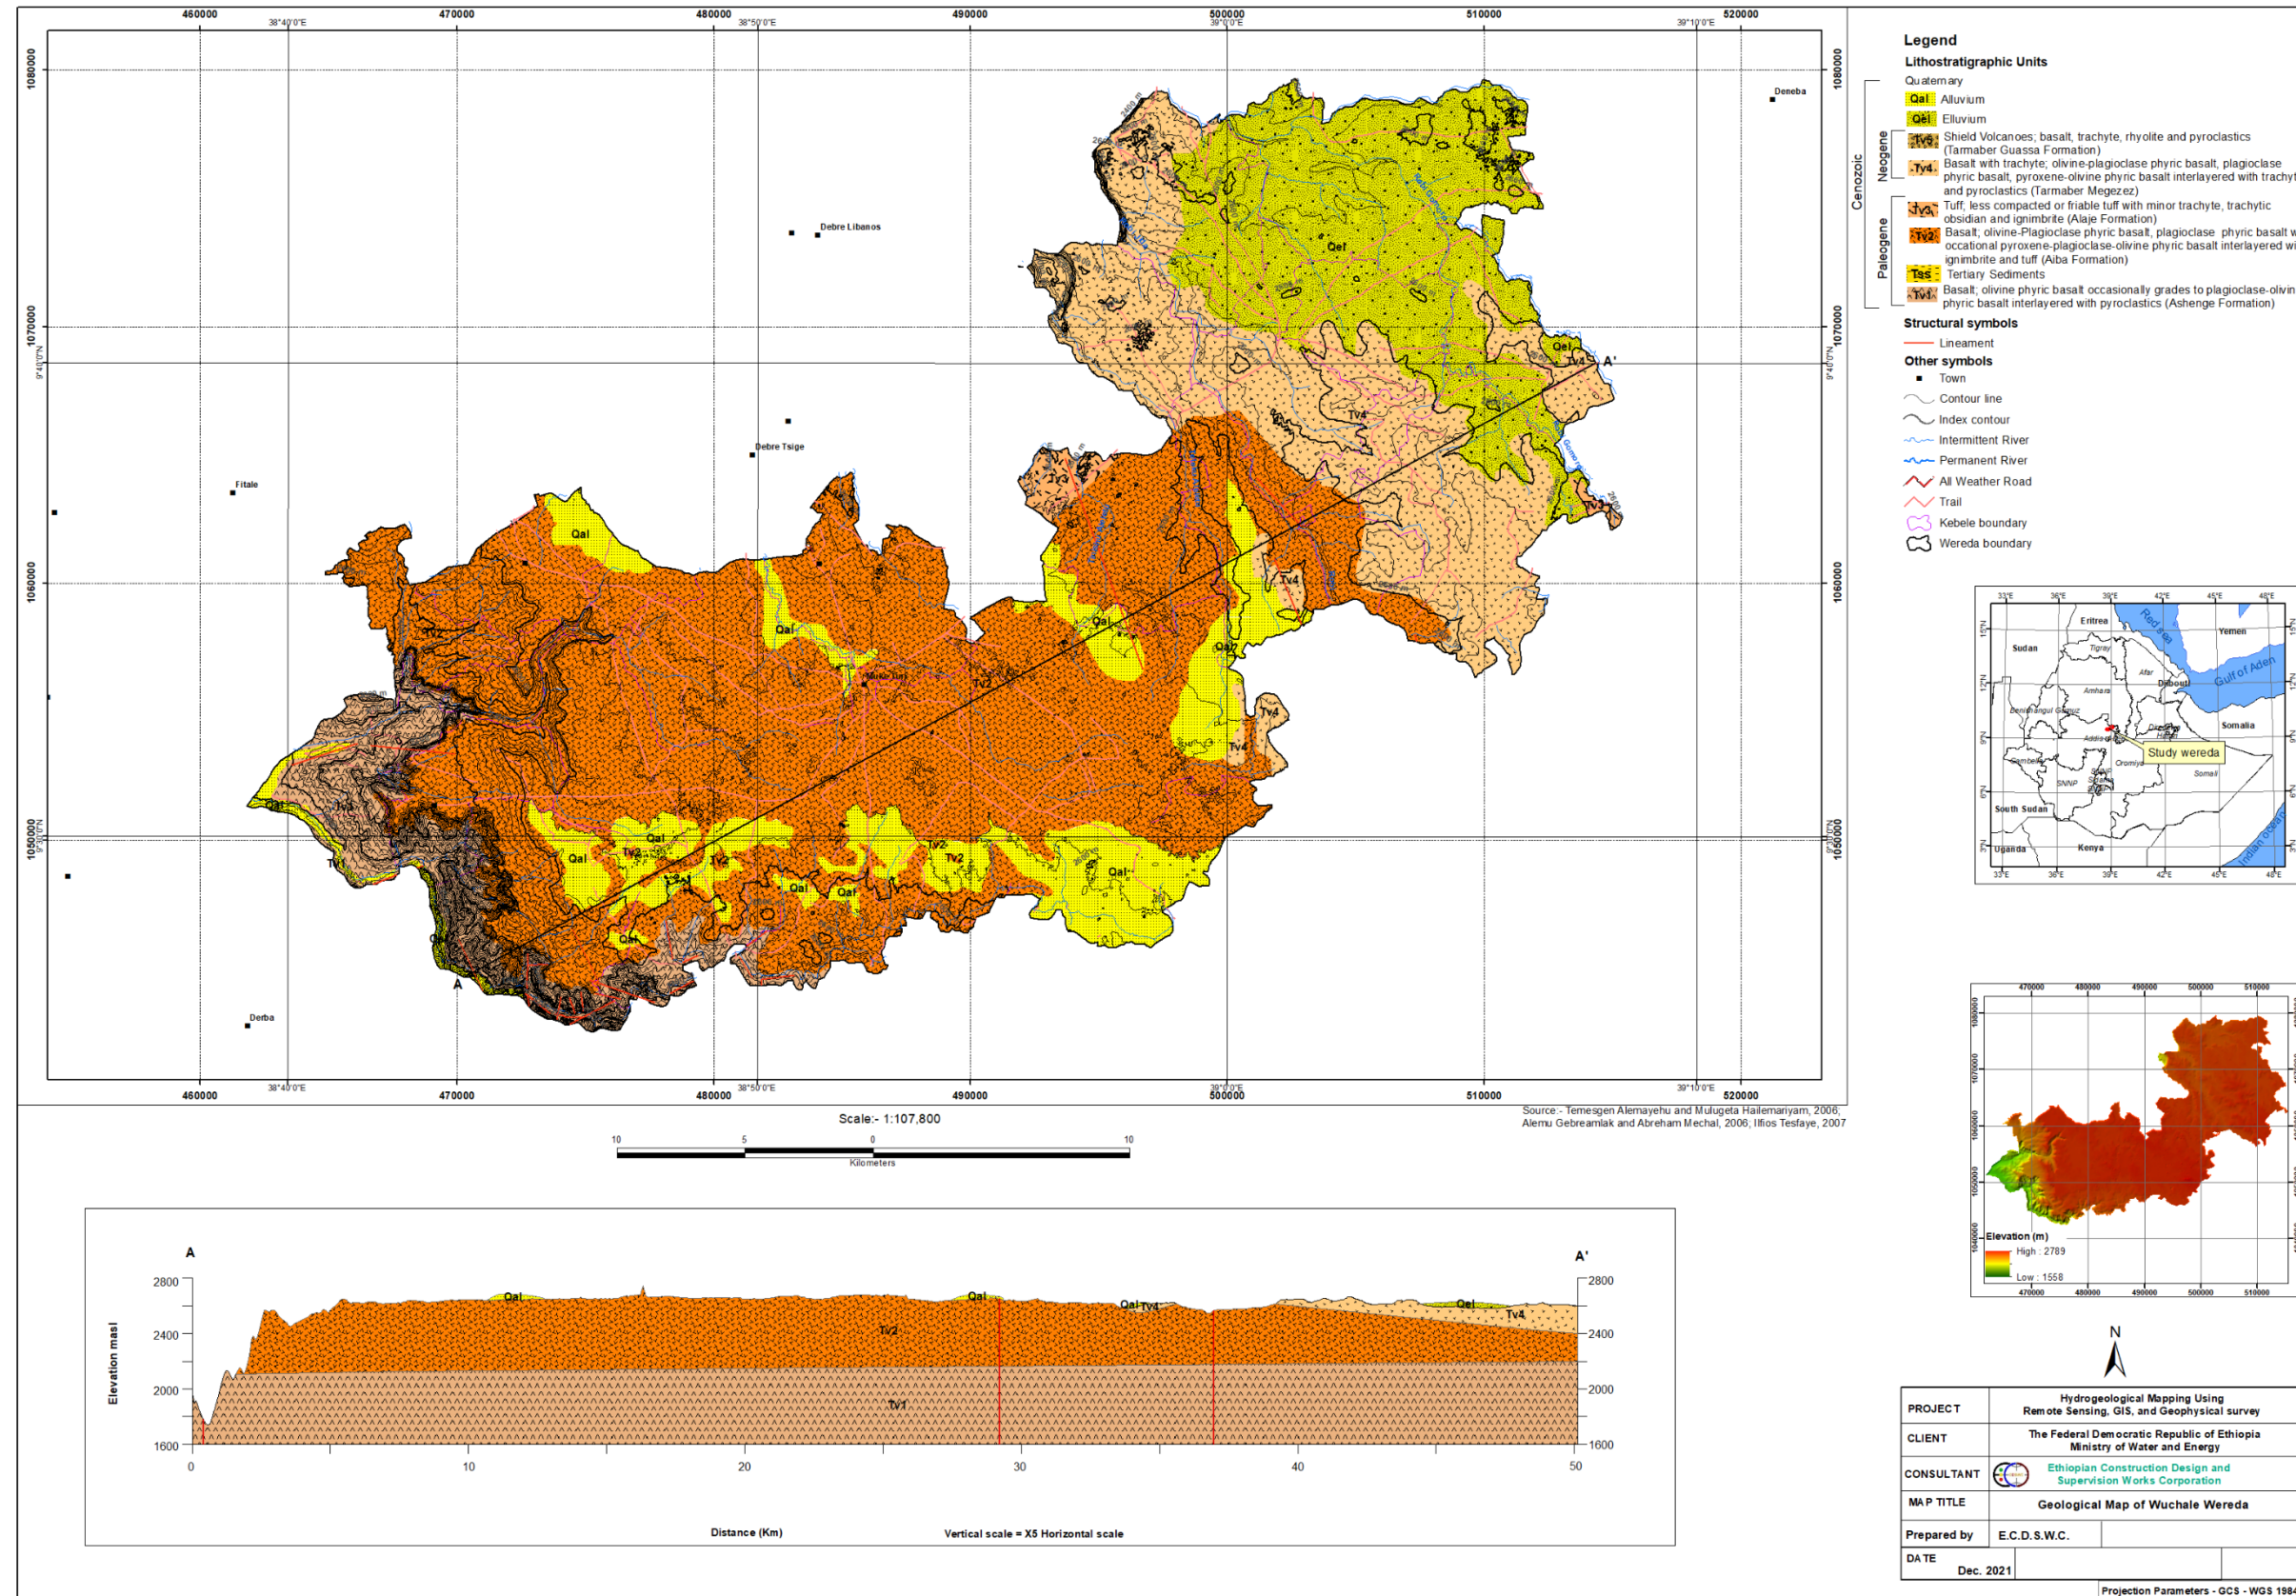

Geologic map and cross section of Dera Wereda

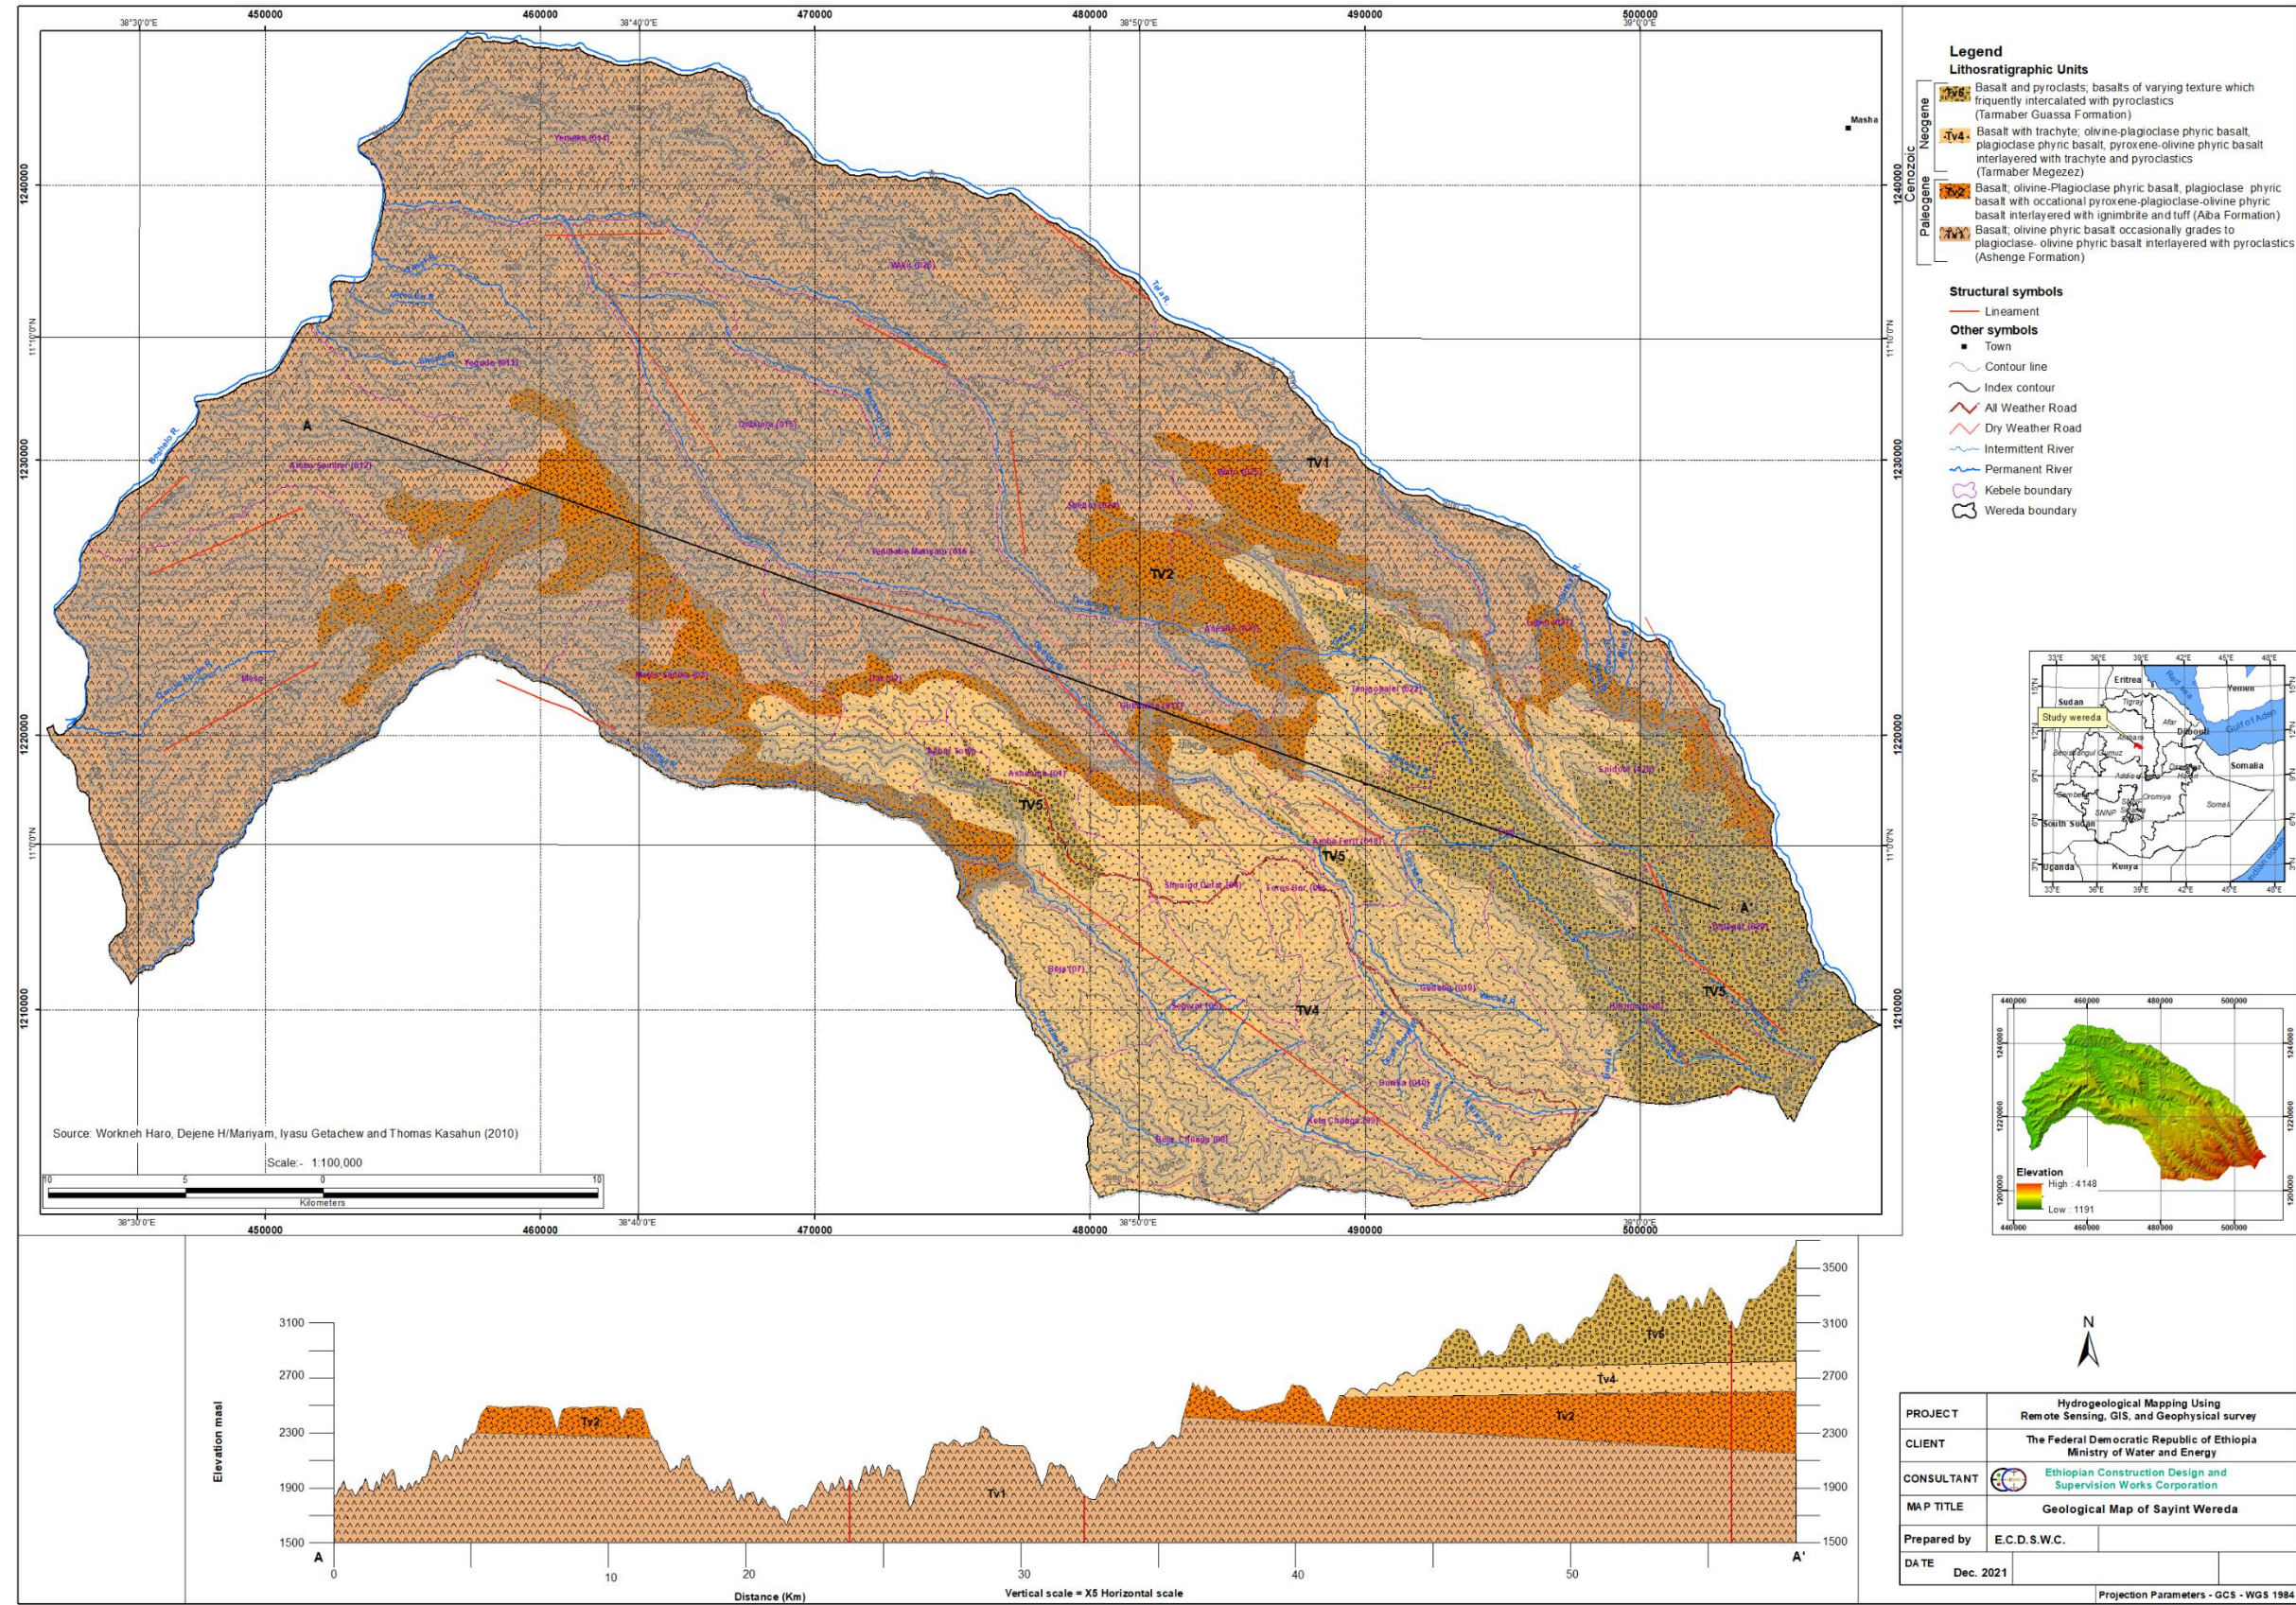

Geologic map and cross section of Girar Jarso Wereda.

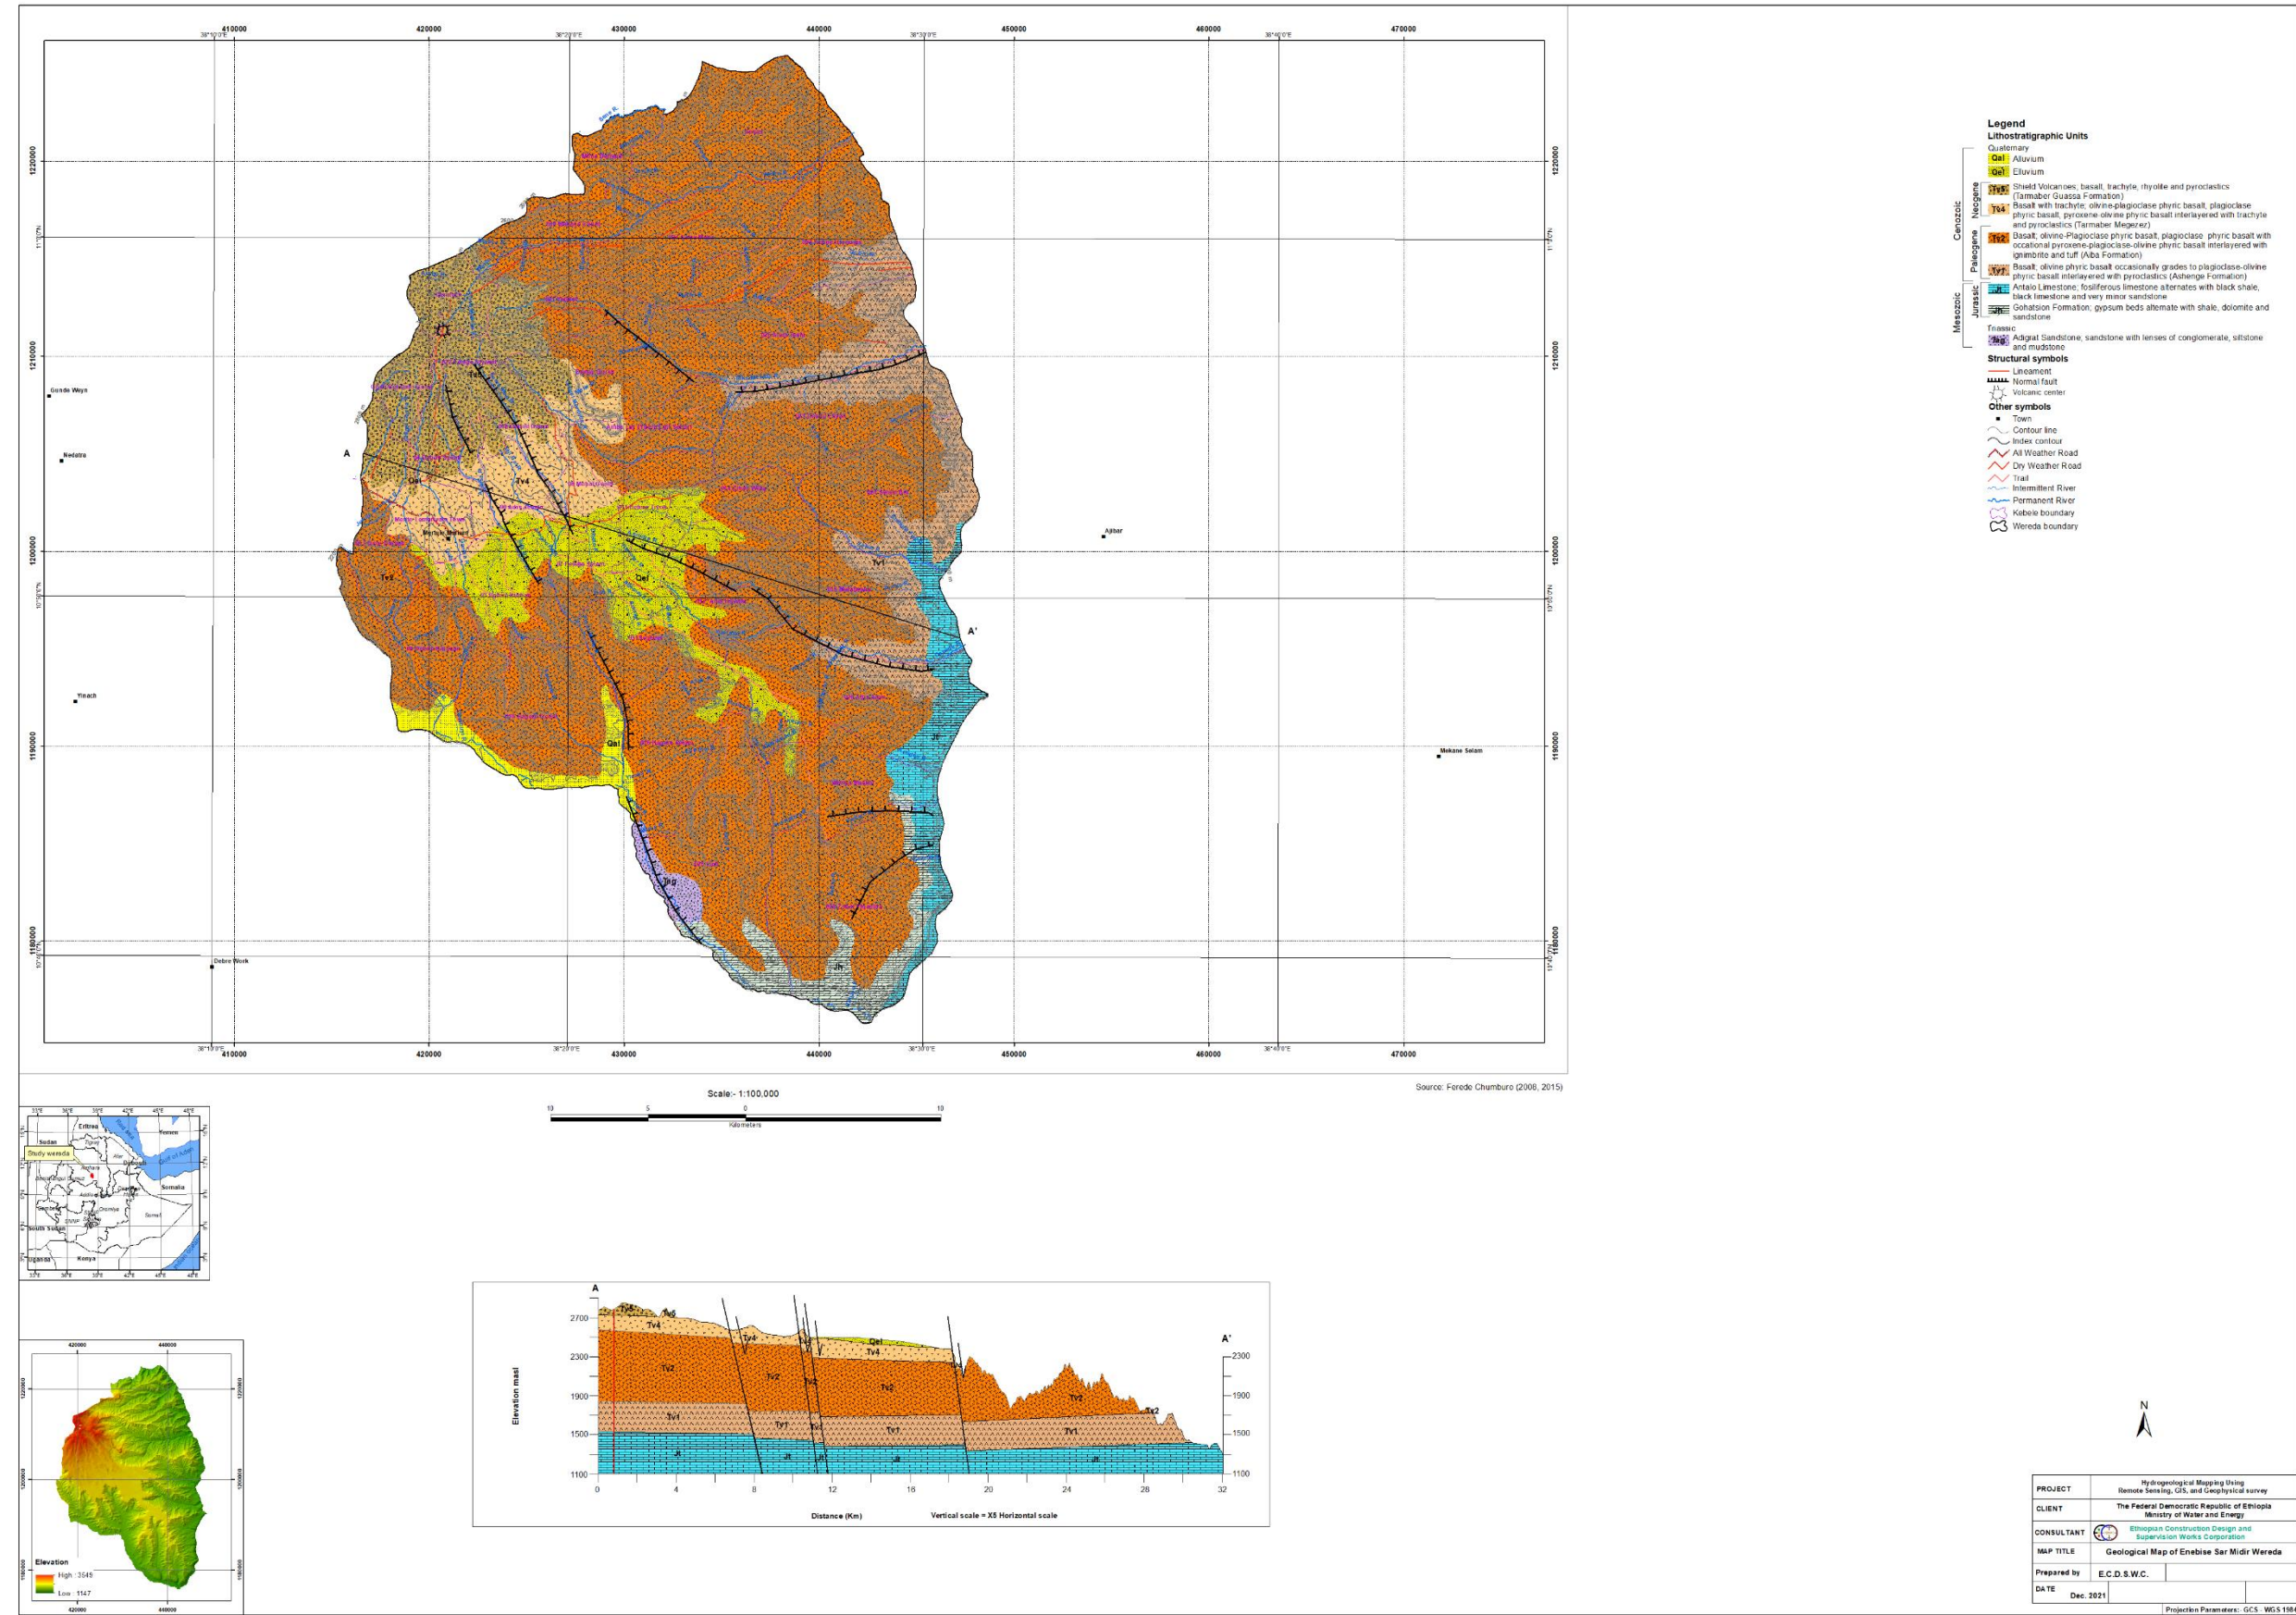

Geological map and cross section of Kuyu Wereda.

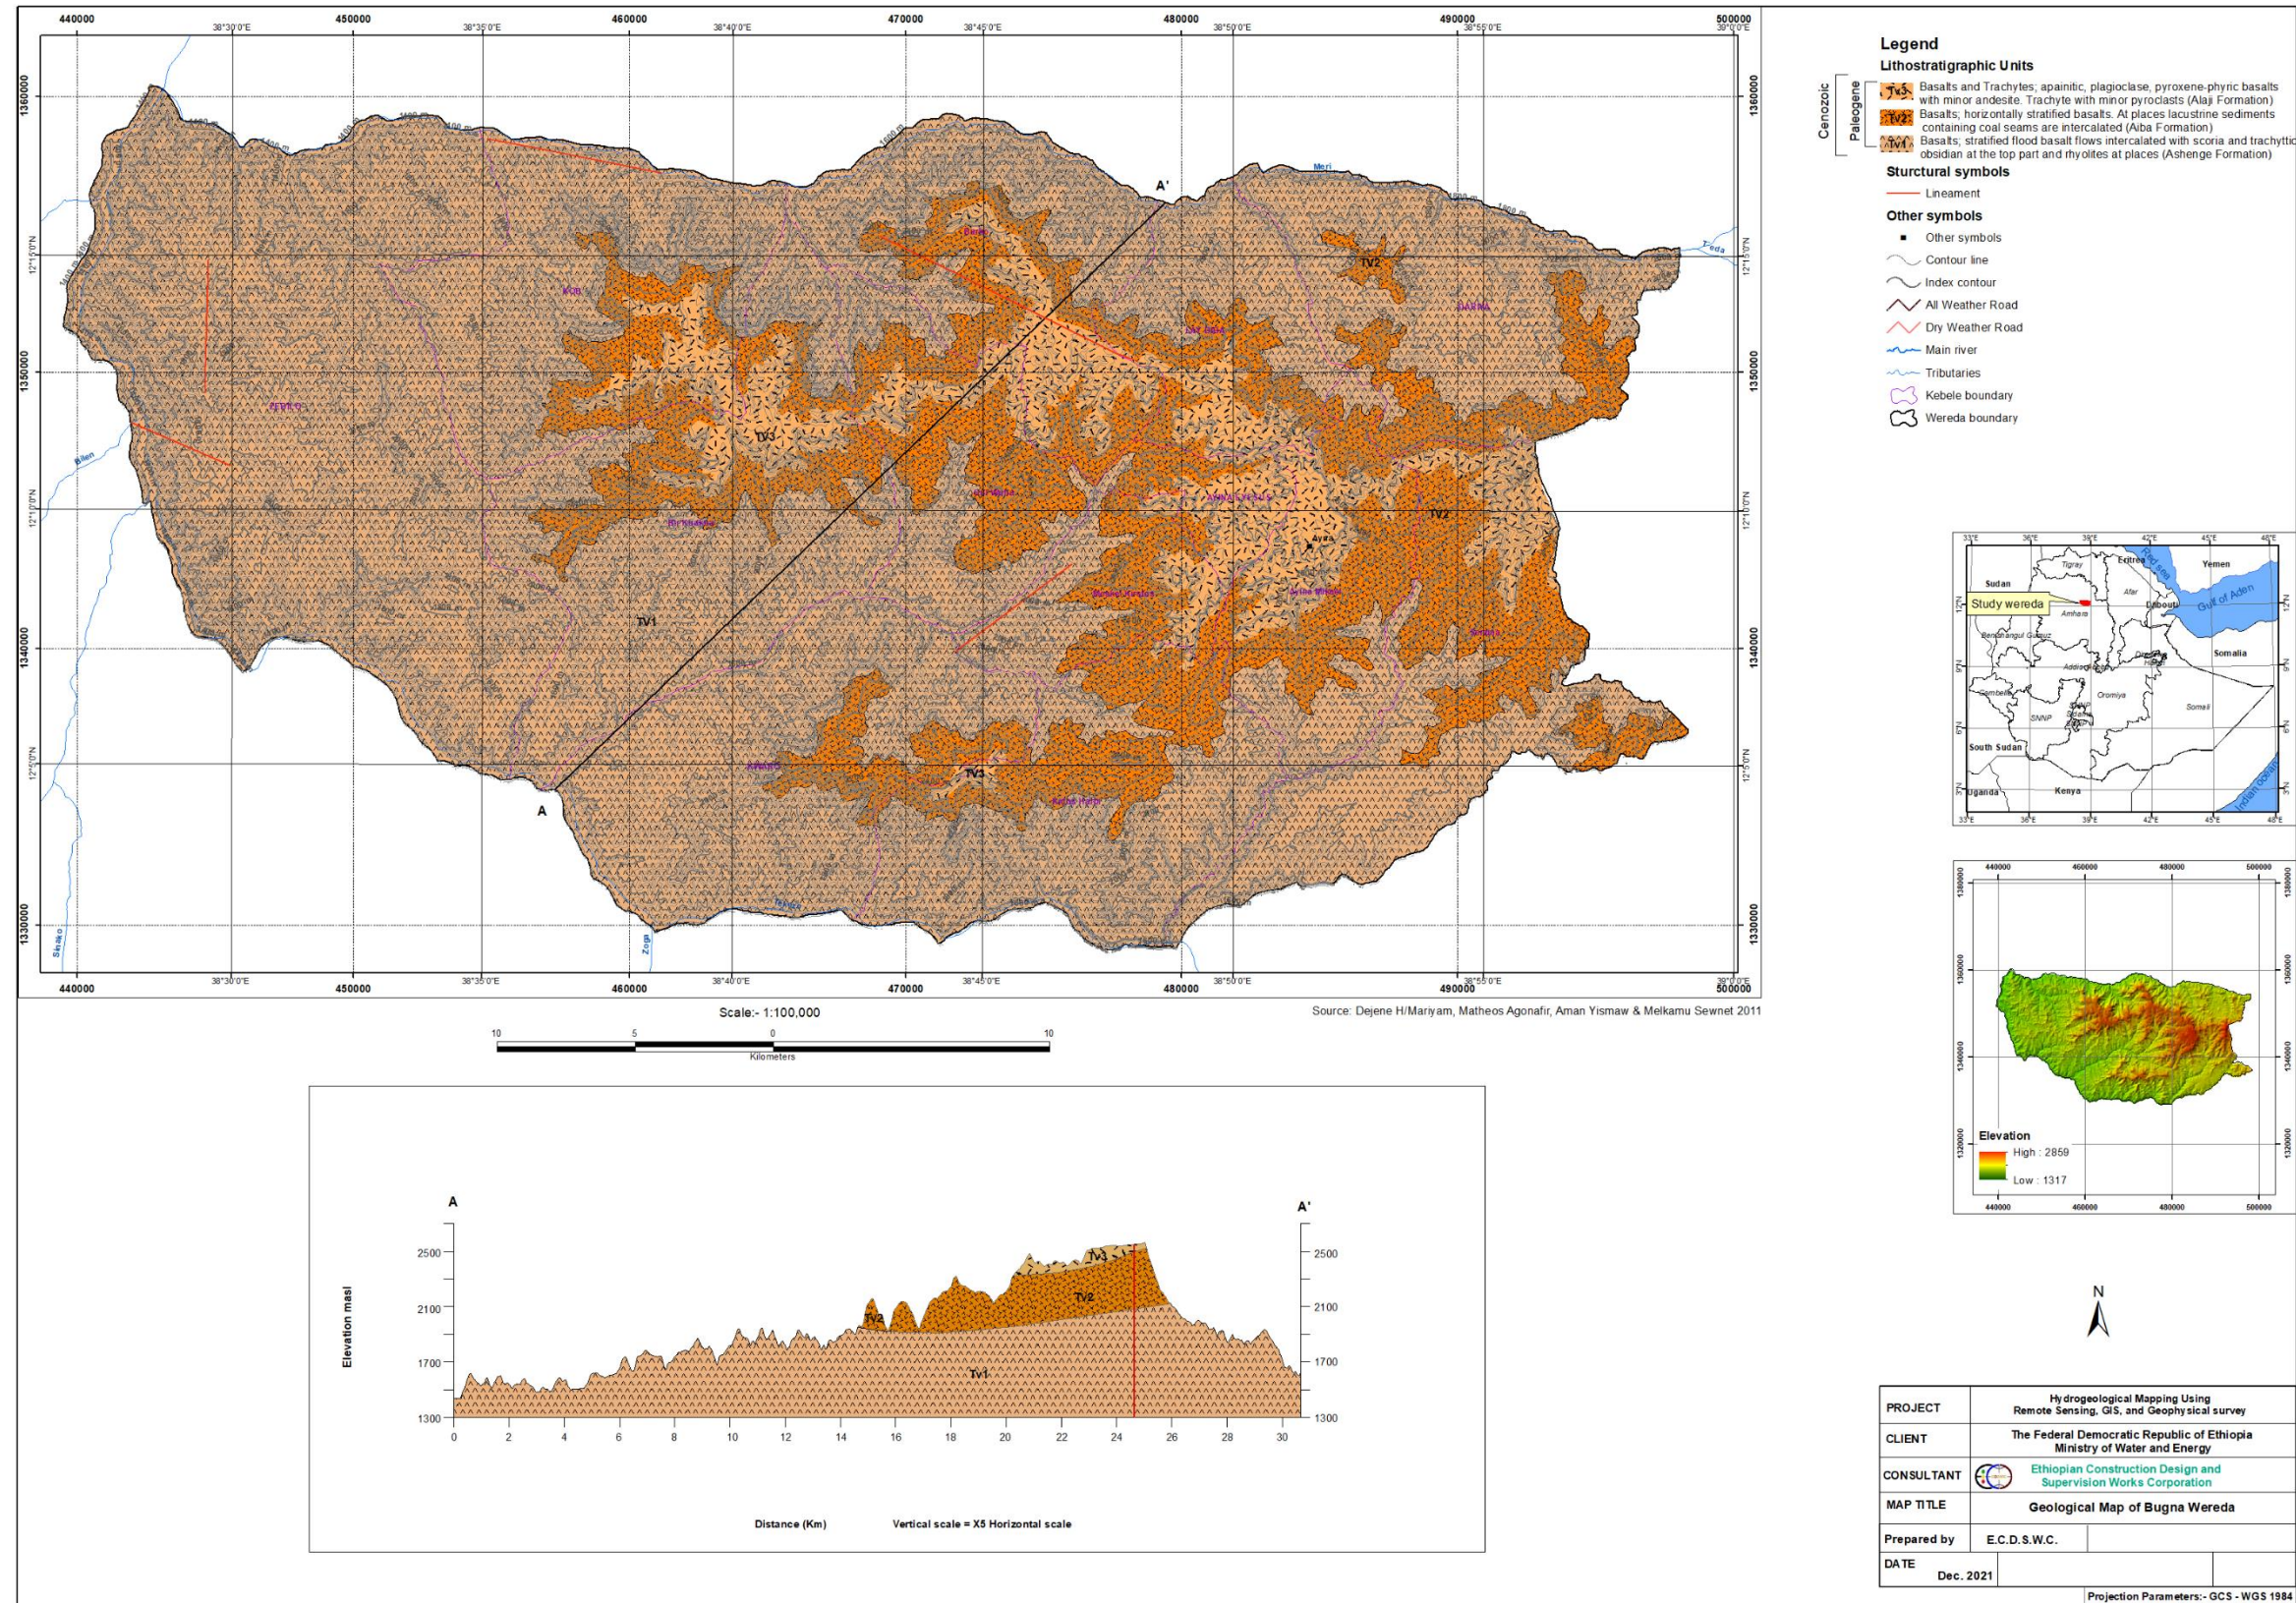

Geologic map and cross section of Wuchale Wereda.

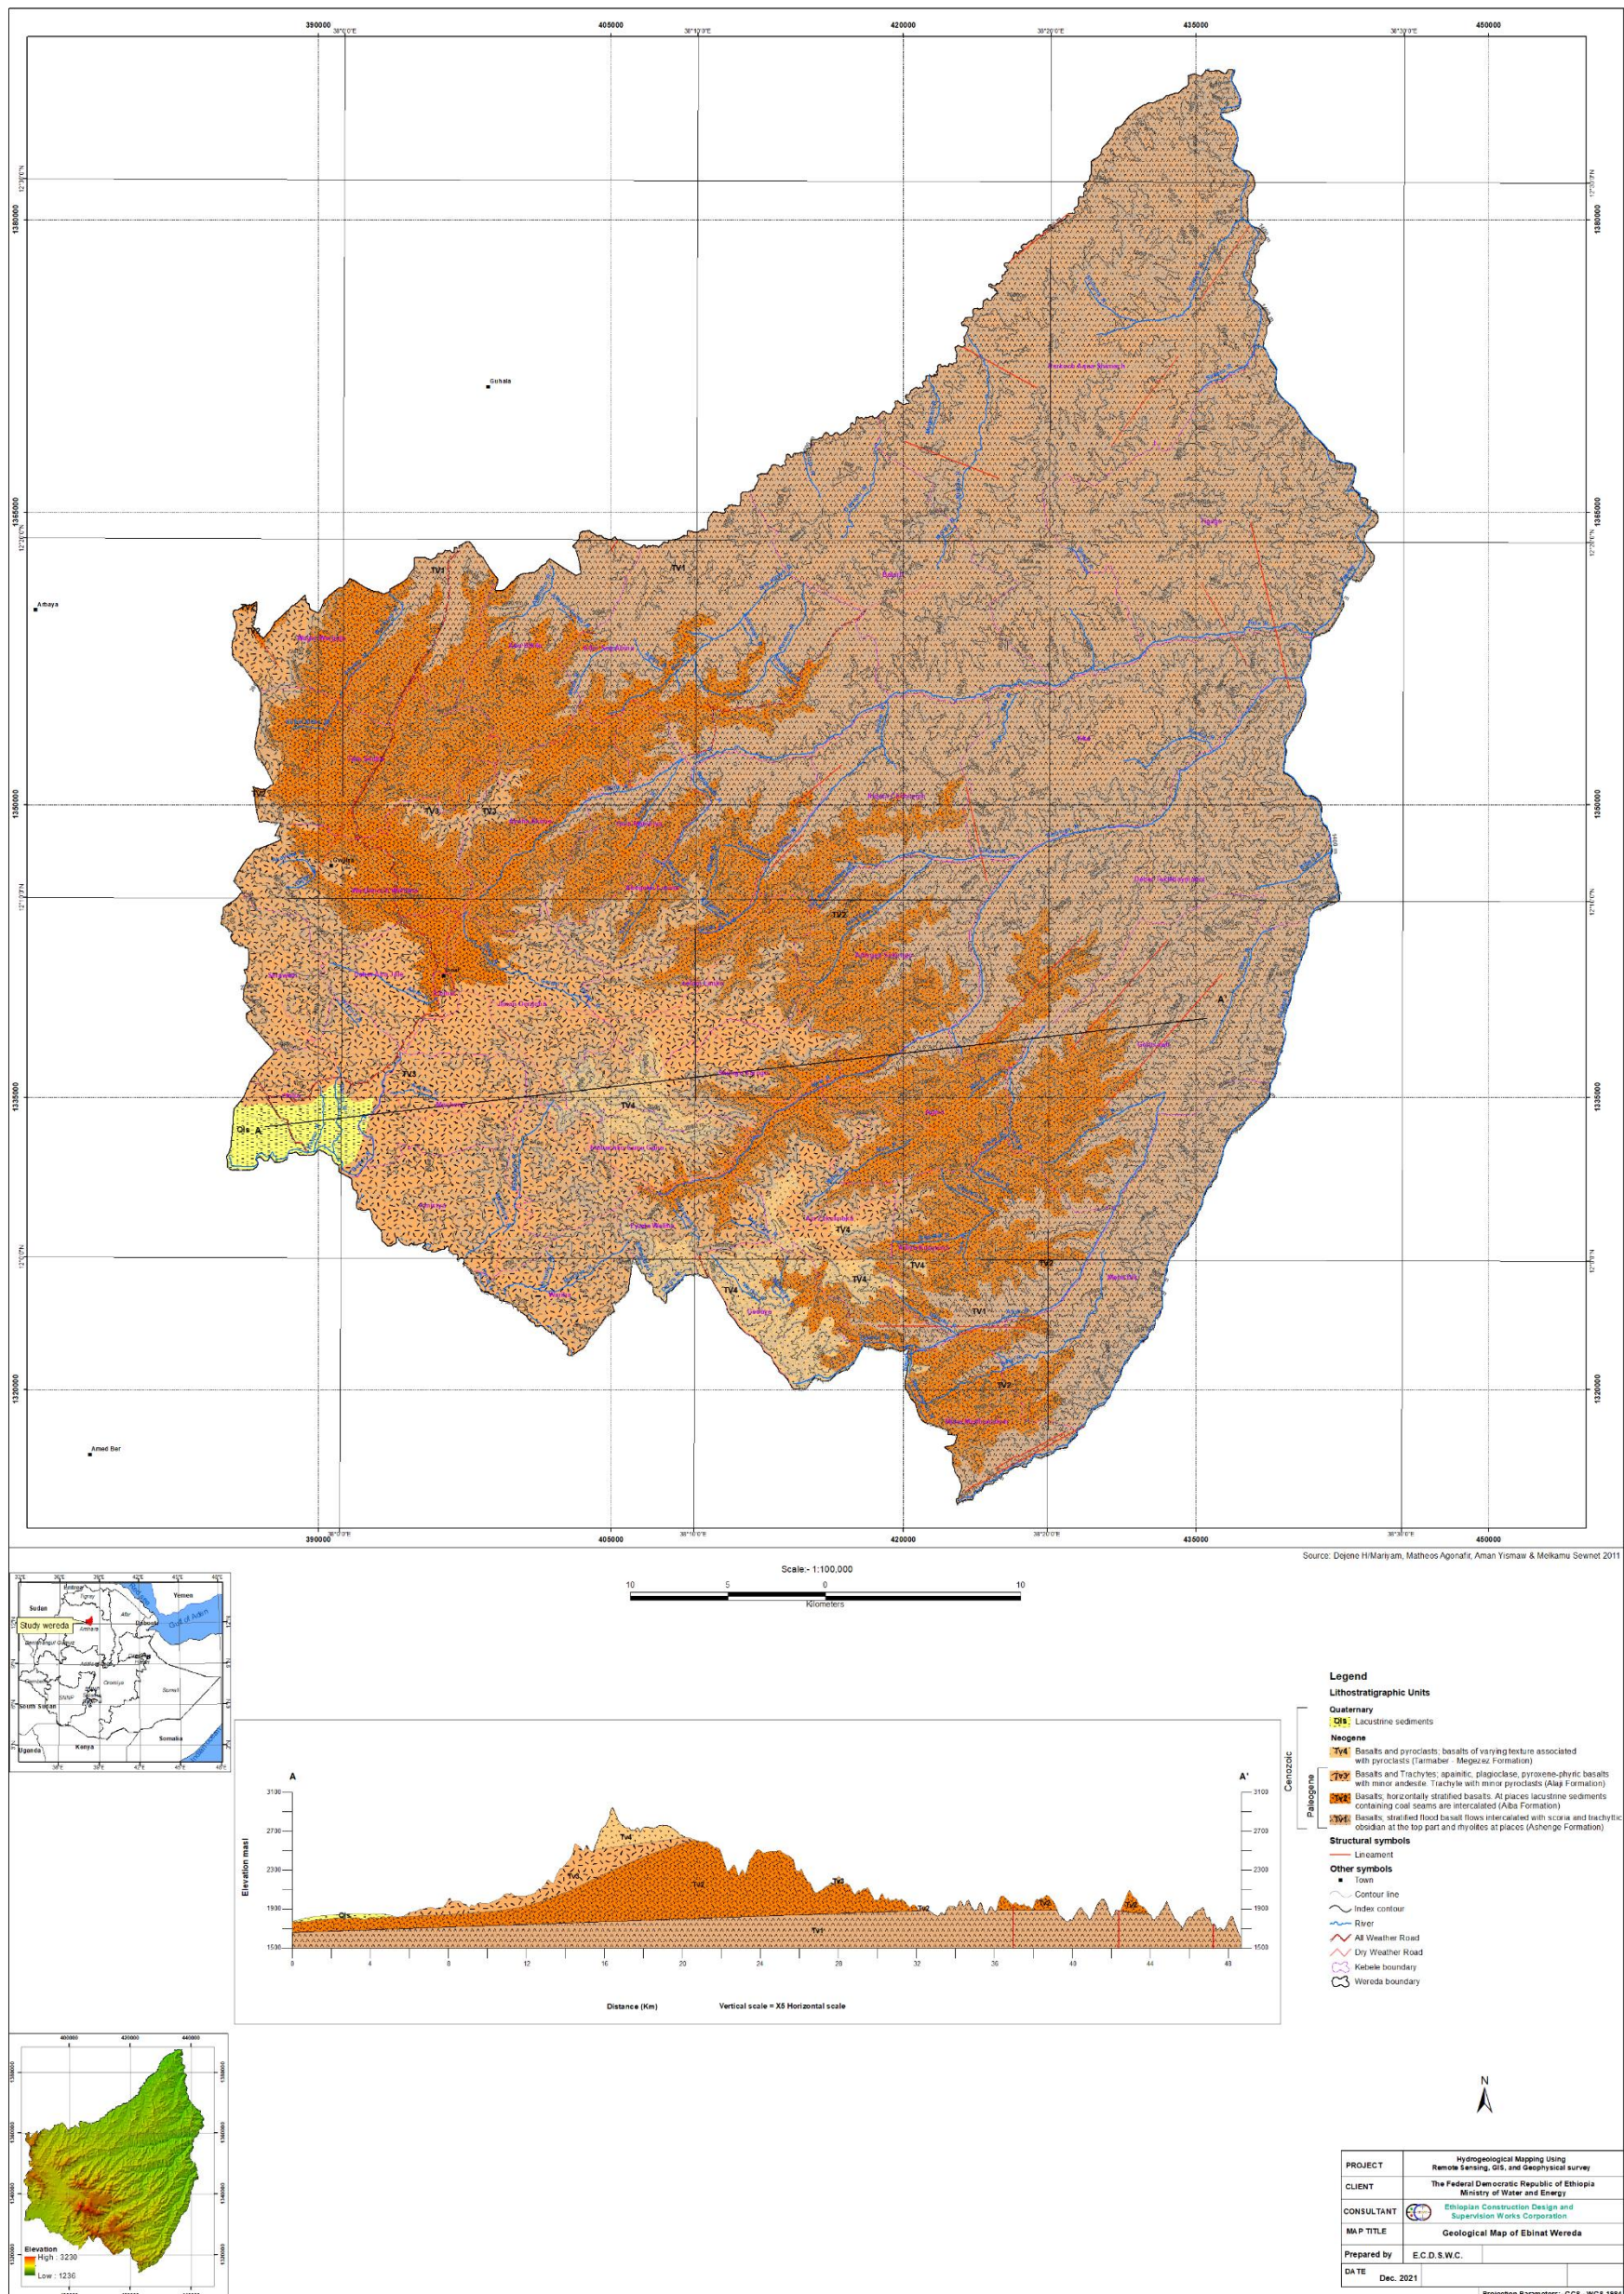

Geological map and cross section of Sayint Wereda.

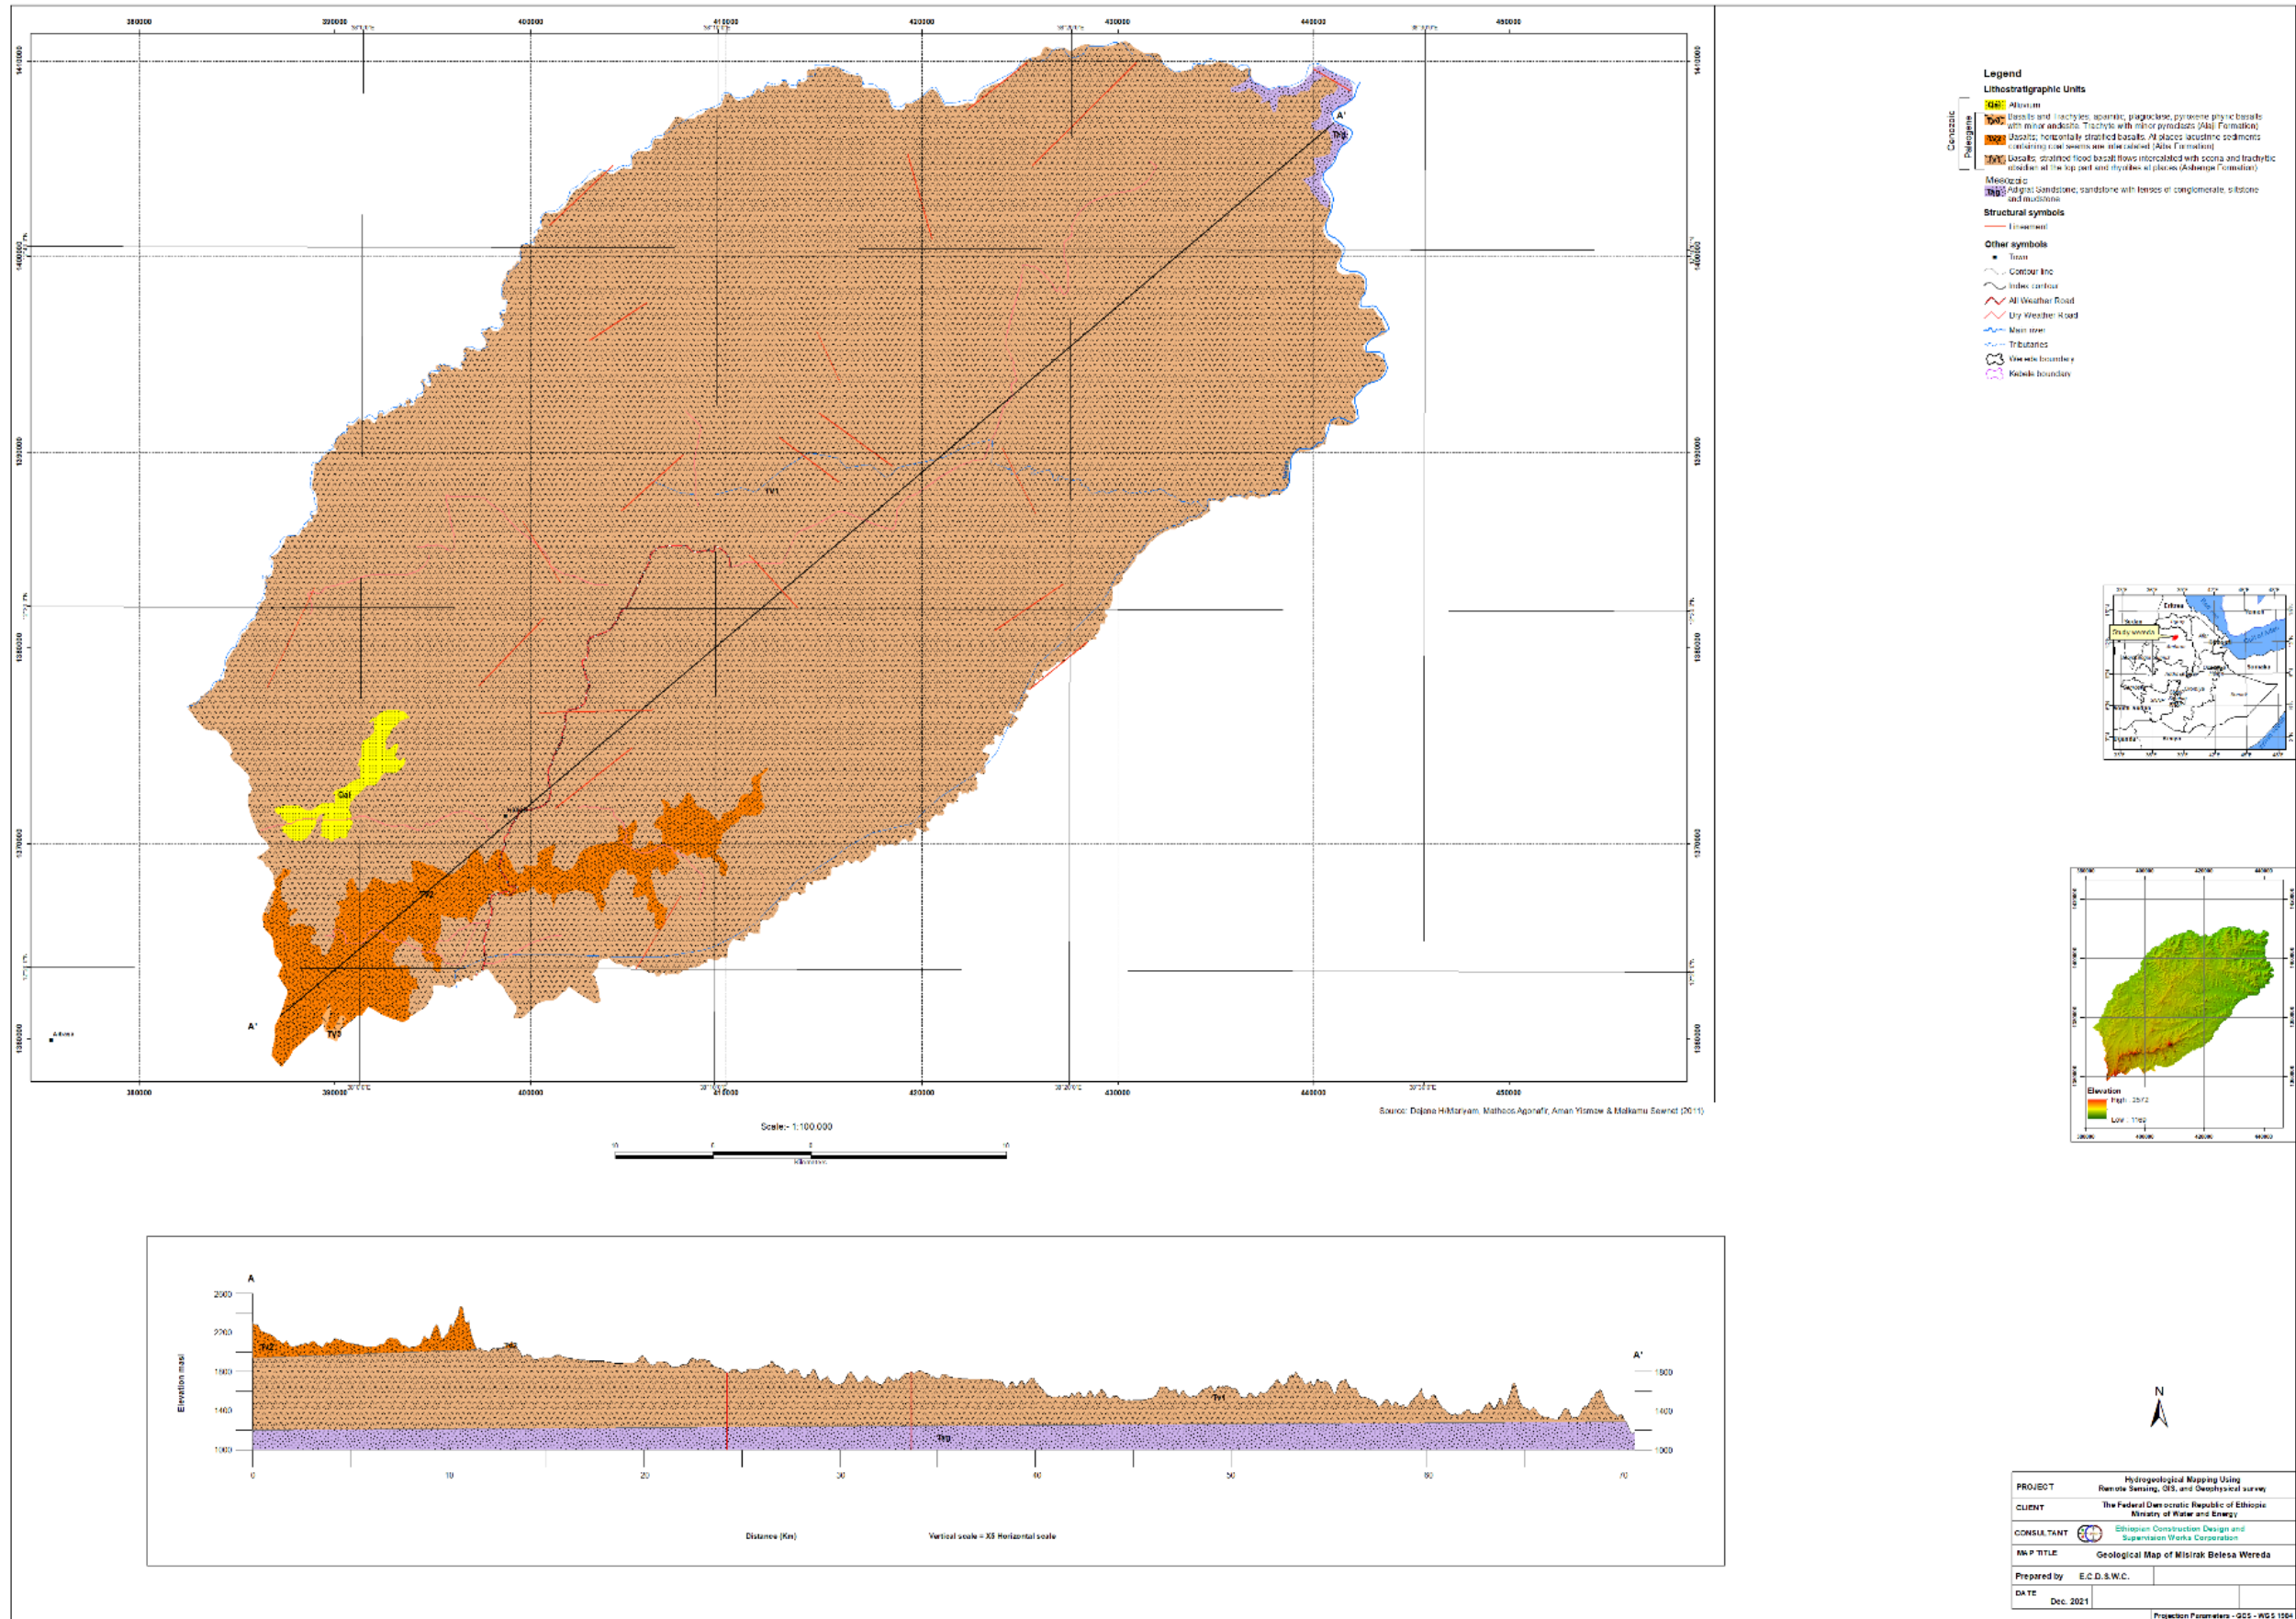

Geological map and cross section of Enebase Sar Midir Wereda.

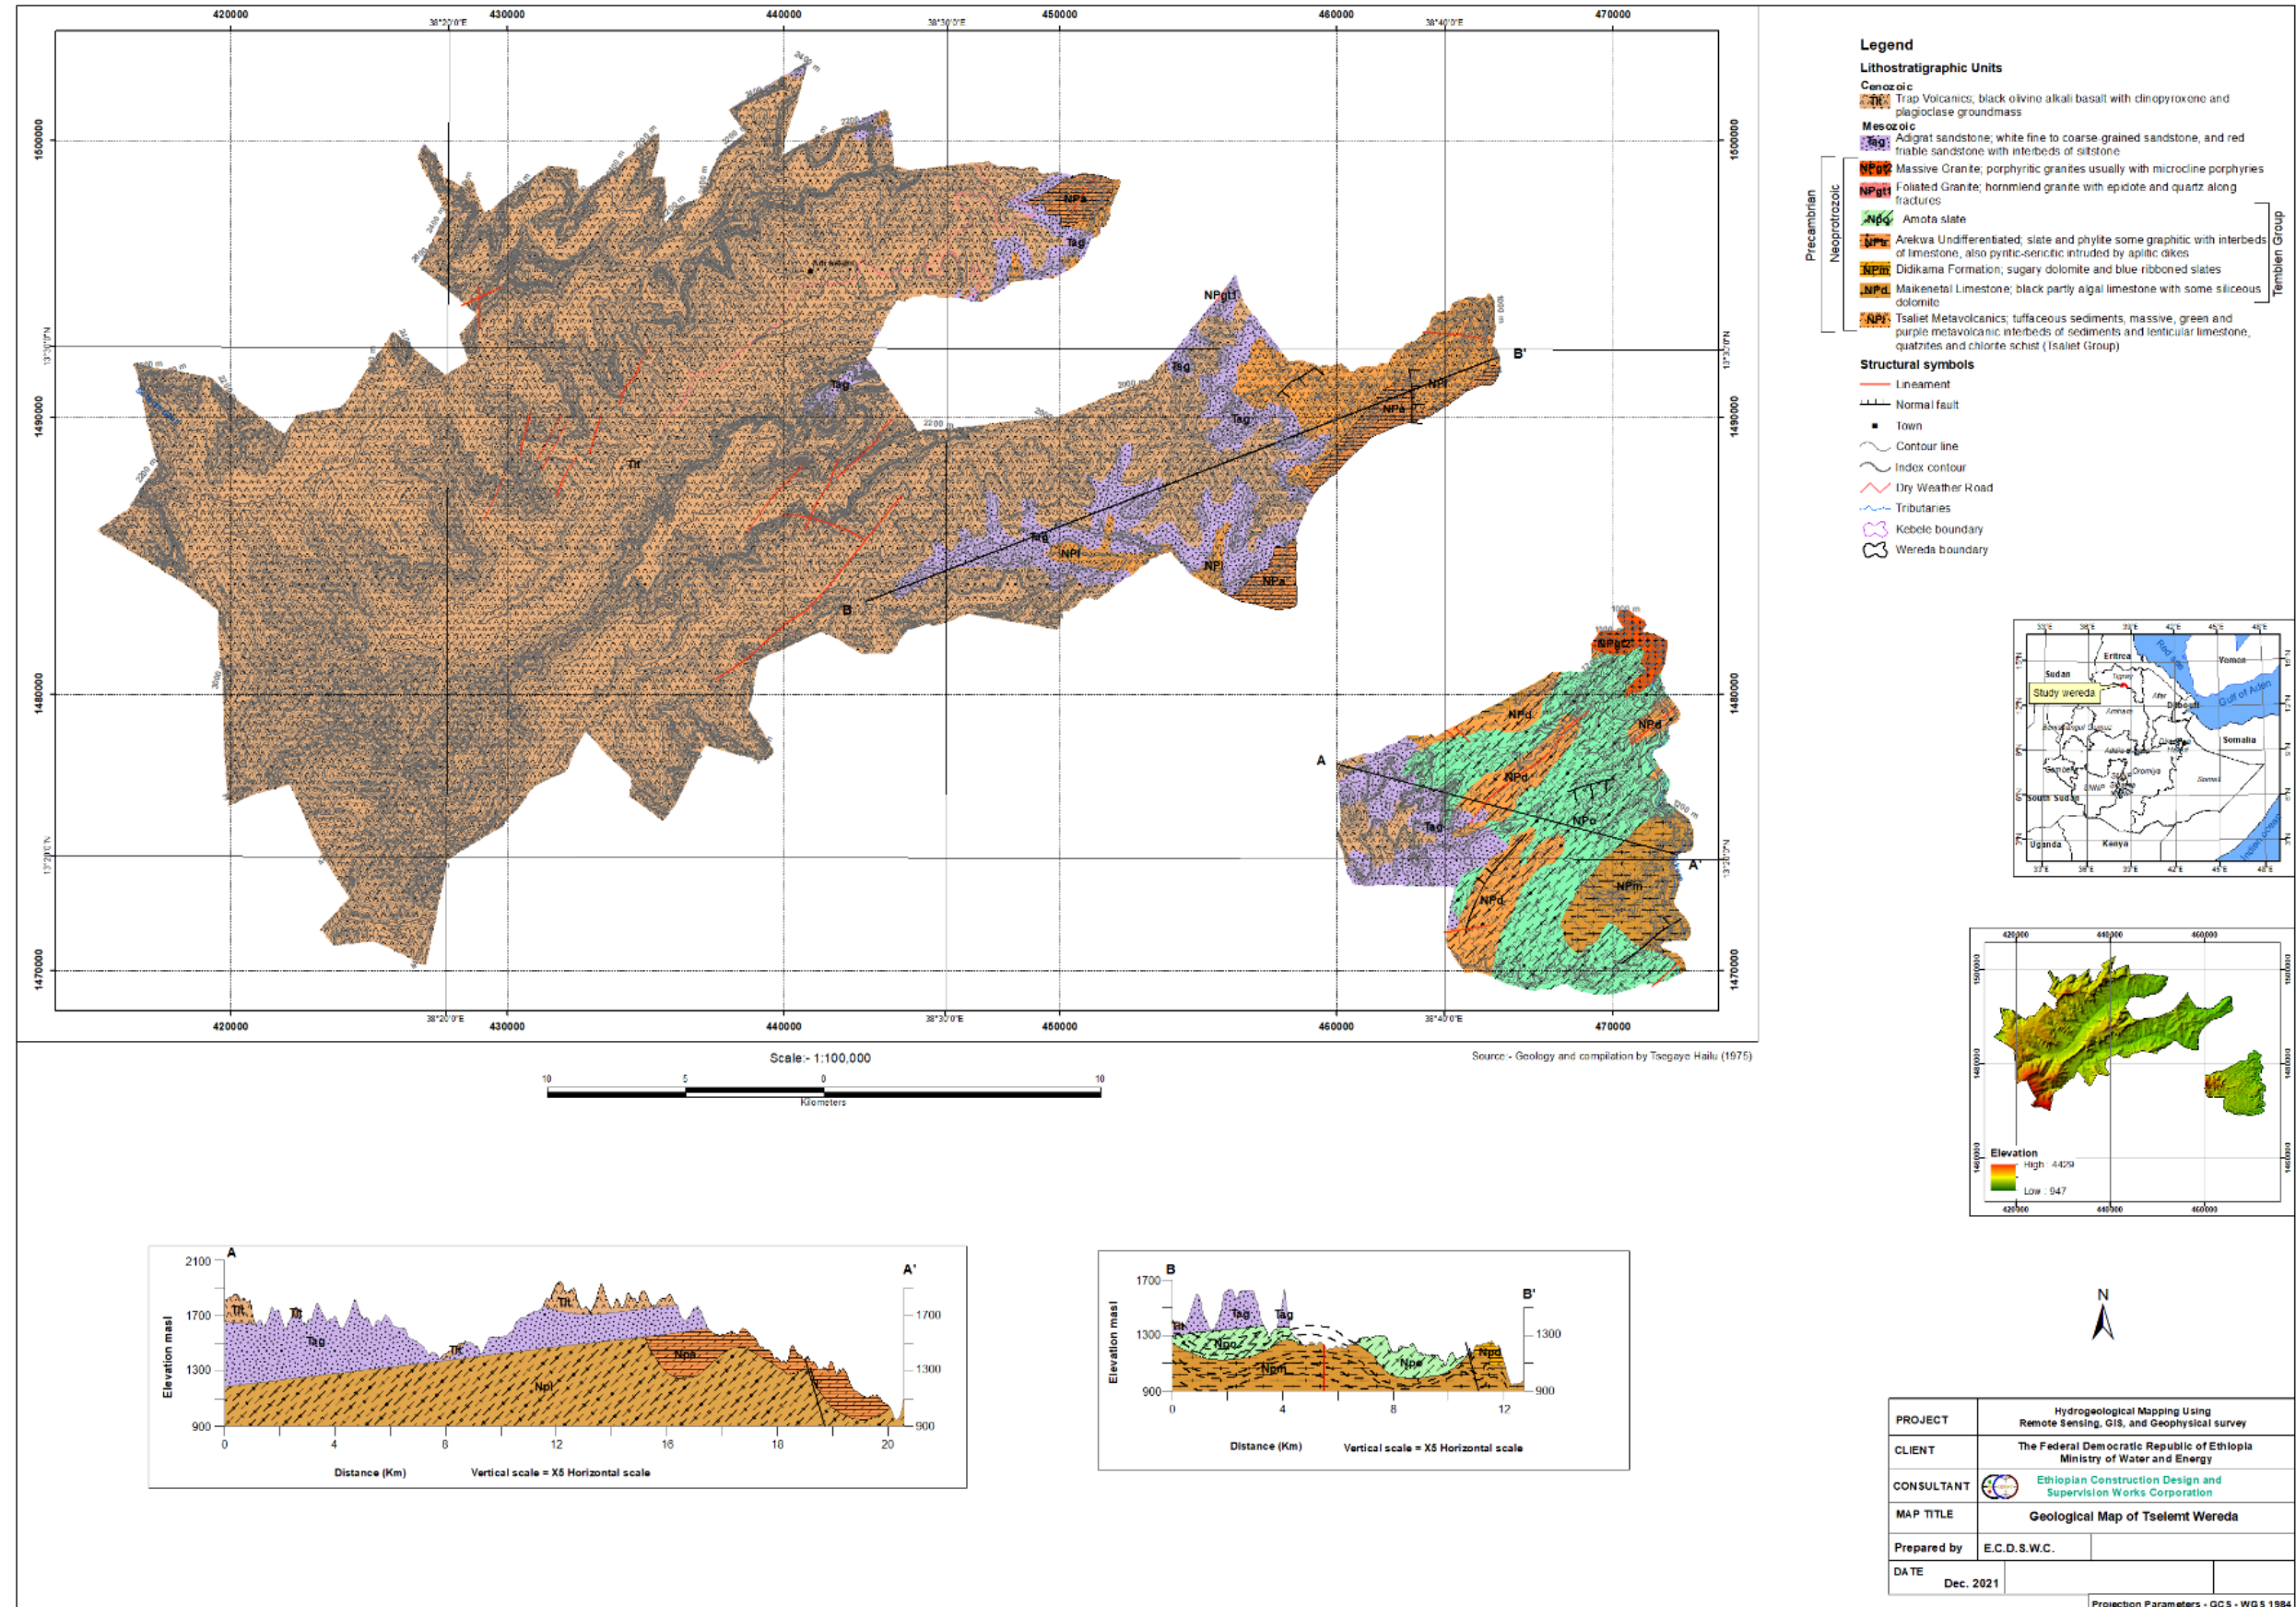

Geological map and cross section of Bugna Wereda

Geological map and cross section of Ebinat Wereda.

Geological map and cross section of Misrak Belesa Wereda.

Geologic map and cross section of Tselemit Wereda
